March 13, 1975

FERMILAB SCANNERS UNCOVER SECRETS ON FILM

Glimpses of the unique regions of high energy physics explored in the Fermilab 15-Foot Bubble Chamber's first experimental runs are beginning to emerge from the Film Analysis Facility on the 9th floor of the Central Laboratory. In the hands of a group of twelve specially-skilled employees lie the clues to this vast reservoir of new knowledge. In their darkened headquarters, the scanners of the Film Analysis Facility combine their visual observations with electronic techniques to analyze film produced by the 15-Foot Chamber when two major experiments ran there, and the film of two experiments run in the 30" Bubble Chamber, in the latter half of 1974.

FAF's present scanning staff consists of Karen Carew, Steve Condon, Barbara Cox,

FERMILAB SCANNERS UNCOVER SECRETS ON FILM

Glimpses of the unique regions of high energy physics explored in the Fermilab 15-

The 15-Foot film is so rich and complex that no completely automated method can be devised to study it. The scanning procedure at Fermilab begins with the sharp observations of the scanners, as the film is run across a lighted table at the scanner's direction, magnified first at 12 times, then 66 times to examine fine details. A beginning scanner is provided a basic set of instructions -- how to identify the interactions and then to record the location and a number of characteristics of the tracks. This is pure scanning, or reviewing, of the film, resembling the assembly of a library catalog of the film's contents. When the interactions have been identified, the scanner must measure the position of about ten points on each track, with a precision digitizing plane. These points are fed by the scanner into the PDP-9/L computer by tapping a foot-controlled device. Eventually, these points are analyzed by sophisticated PDP-10 programs to produce values for the momentum and direction of each track.

FAF's present scanning staff consists of Karen Carew, Steve Condon, Barbara Cox,

The Road to LArTPCs

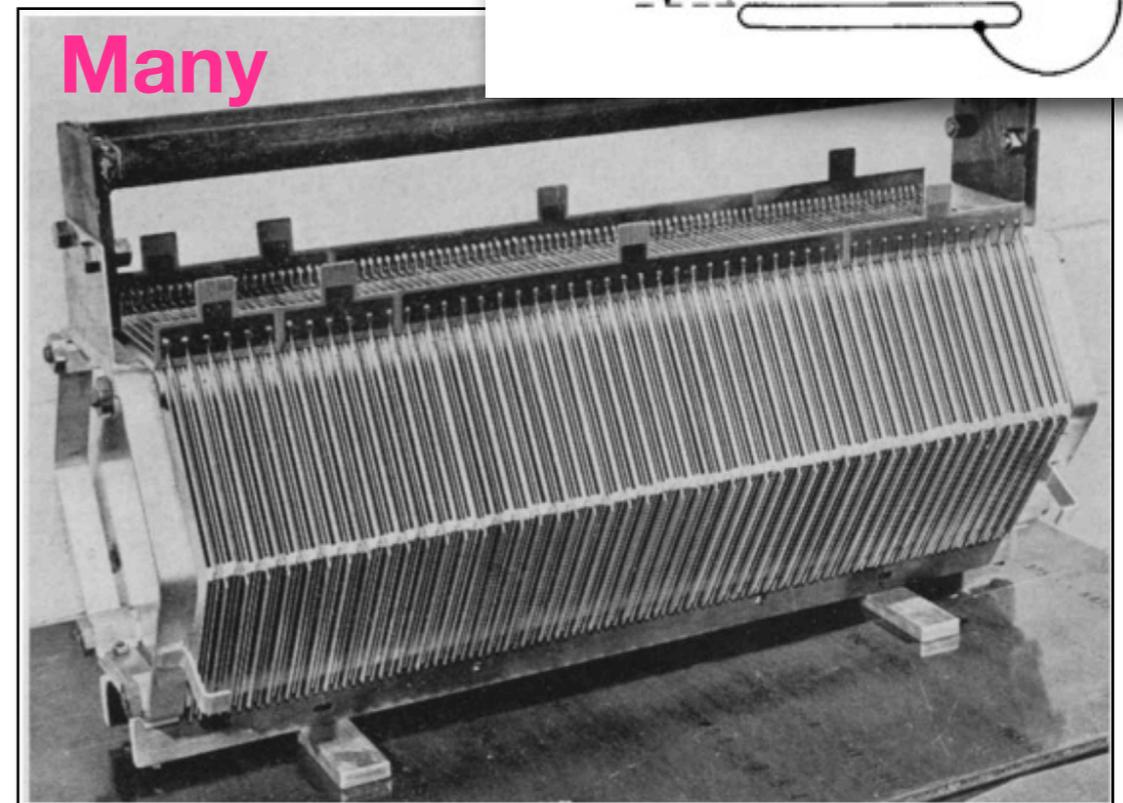

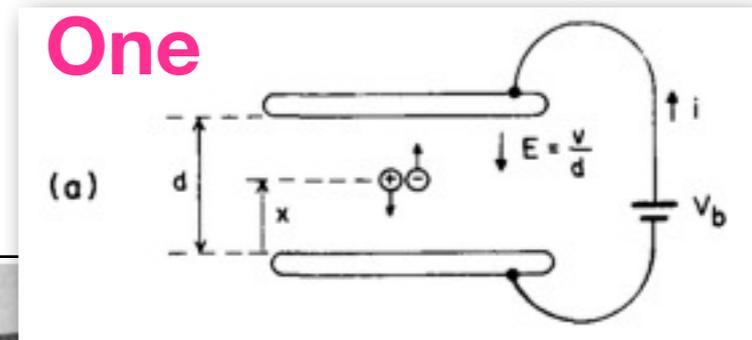

- 1968: L.W. Alvarez first proposes the use of Liquid Noble Gases for particle detectors
- 1974: W. Willis and V. Radeka propose LAr ionization chambers
 - Idea was to use sampling plates in LAr for calorimetry

Benefits of LAr:

- it is dense (1.4 g/cm^3);
- it does not attach electrons;
- it has a high electron mobility ($\sim 5 \text{ mm}/\mu\text{s}$ at 1 kV/mm);
- the cost is low ($\$0.14 \rightarrow 0.50/\text{kg}$, depending on source and quantity);
- it is inert, in contrast to flammable scintillators;
- it is easy to obtain in a pure form and easy to purify;
- many electronegative impurities are frozen out in liquid argon.

The disadvantage is that the container must be insulated for liquid-argon temperature (86 K).

Willis & Radeka, NIM 120 (1974)

The Road to LArTPCs

- 1974: D. Nygren proposes the time-projection chamber

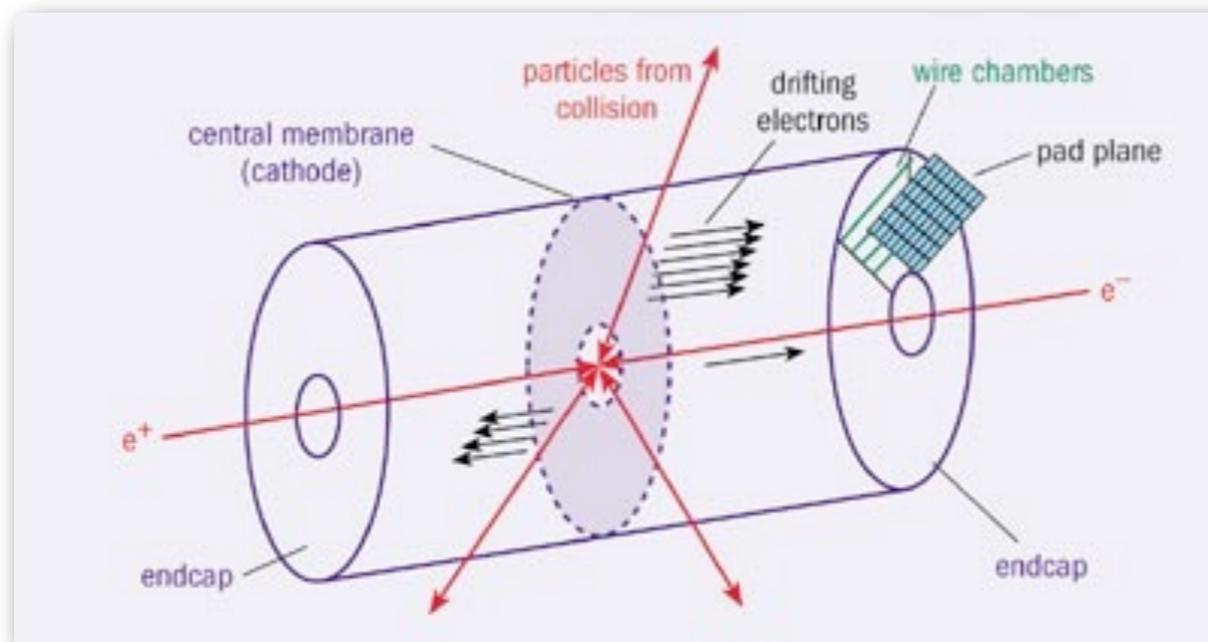

- For the PEP collider at SLAC

- Gas mixtures (e.g. Ar+Methane)

PEP-144-15

Stolen from T. Miceli

Particle Interaction in LAr: Scintillation Light

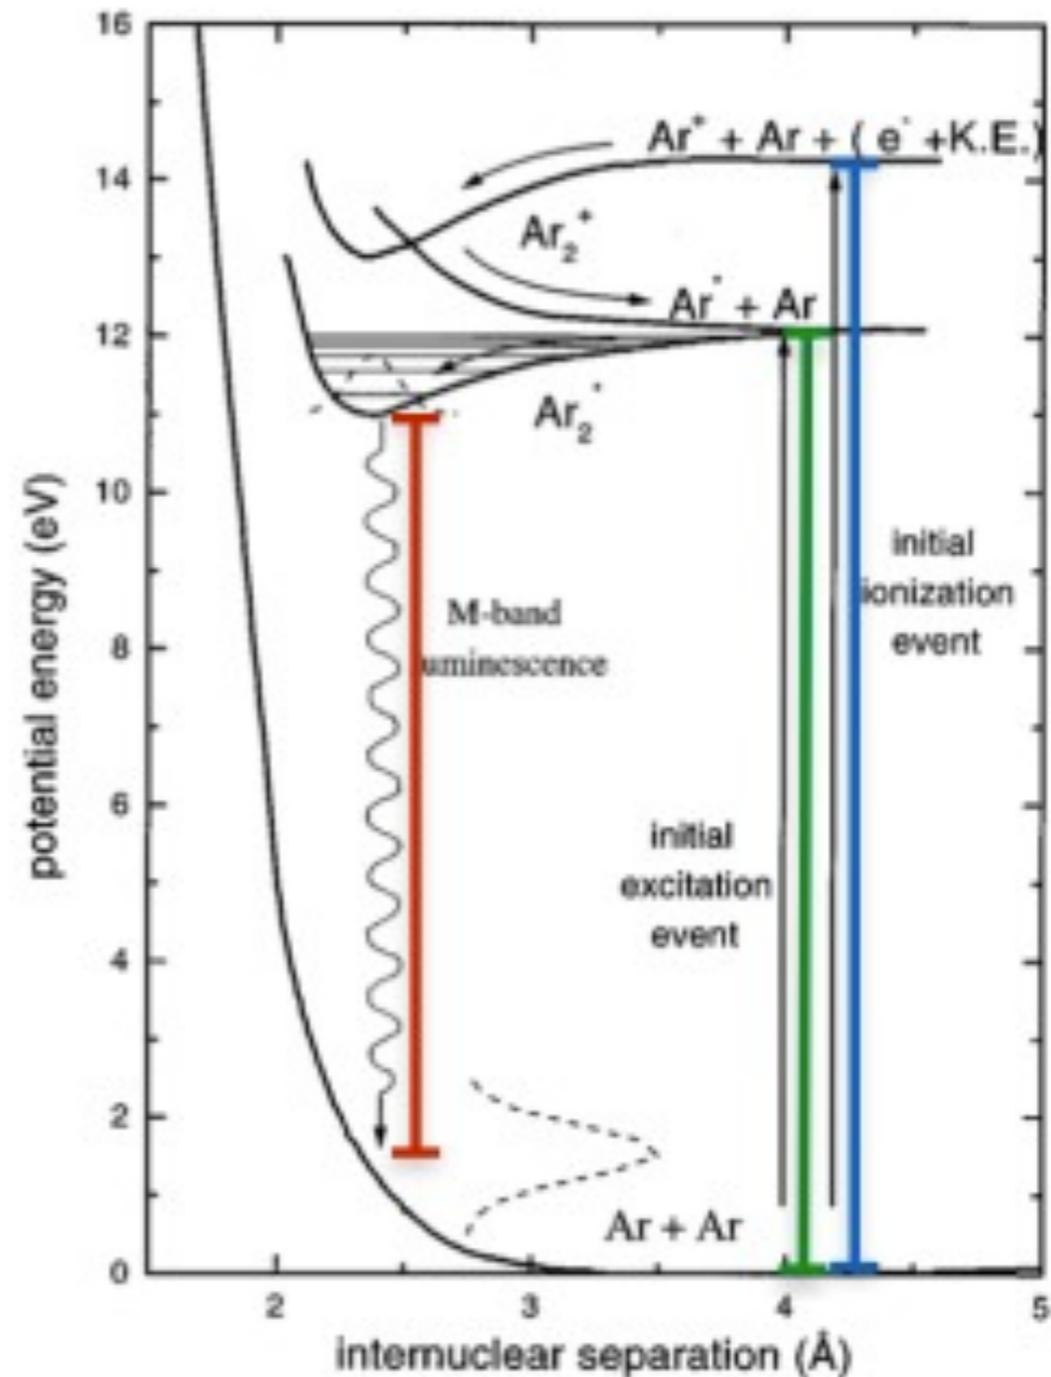

- **Red:** Energy of scintillated photon
- **Green:** Energy of excited Ar molecule
- **Blue:** Energy of ionized pair
- The red is less than the other two
 - The scintillated photon is not energetic enough to put the argon into an excited state
- So argon is transparent to its scintillation light

Signal Dependence on E Field

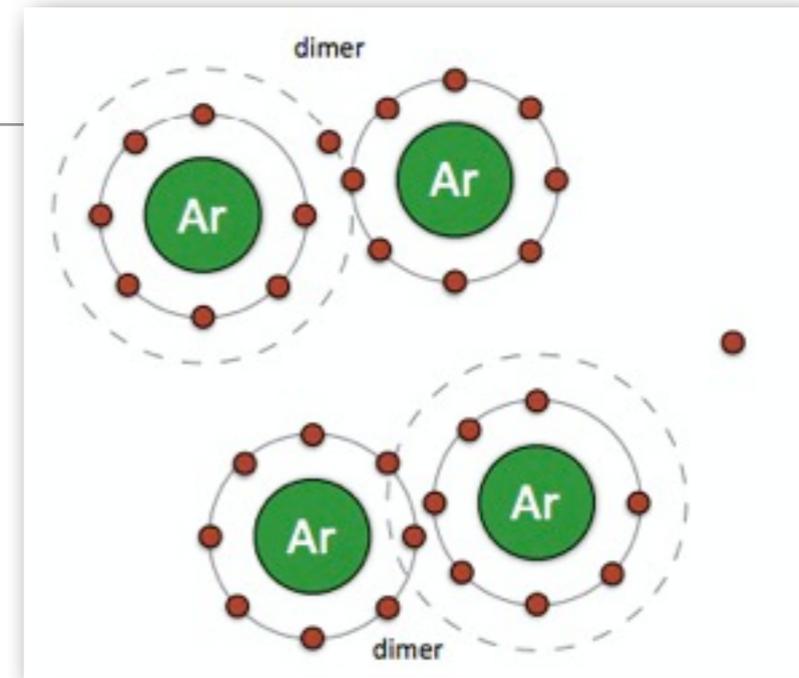

Signal Dependence on E Field

- If the LAr is in an E field, we can drift some of these liberated electrons away before they are reabsorbed

Signal Dependence on E Field

- If the LAr is in an E field, we can drift some of these liberated electrons away before they are reabsorbed
- The amount of these signal electrons depends upon the electric field:

- More electric field = more electrons
- Less field = more recombination (more light emitted from **recombination**)

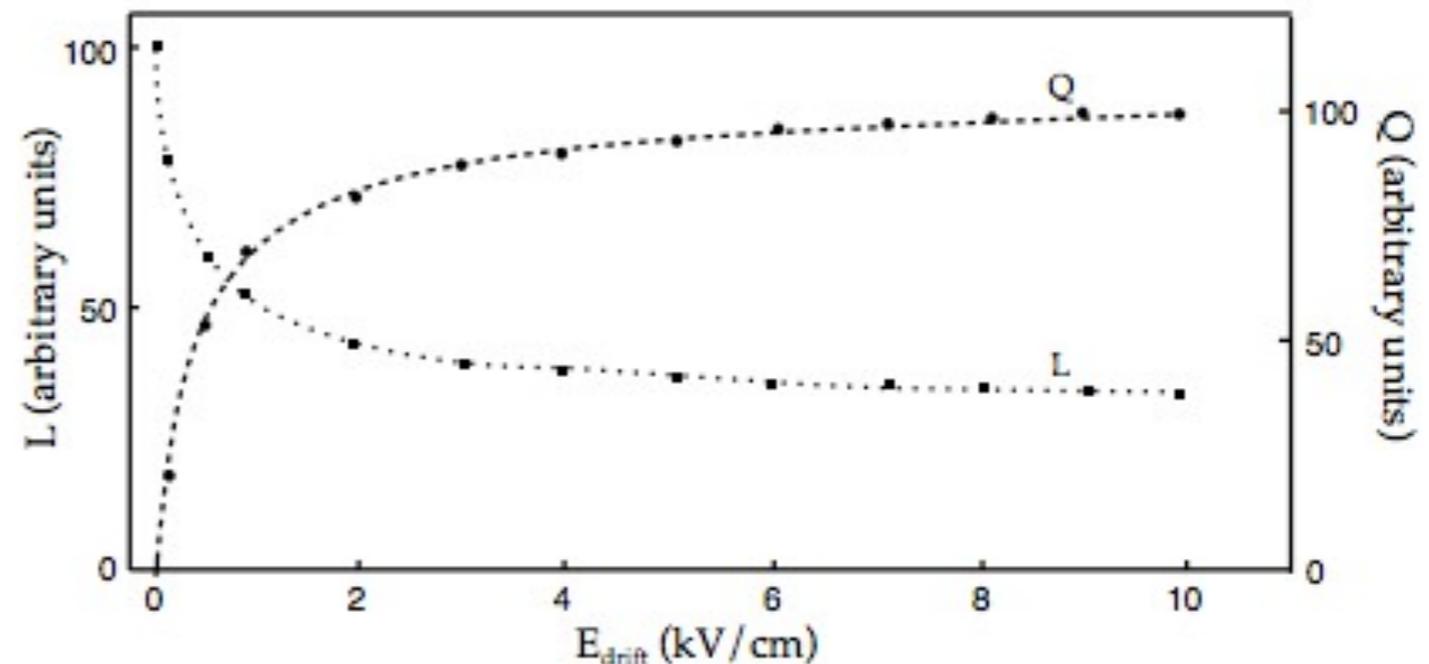

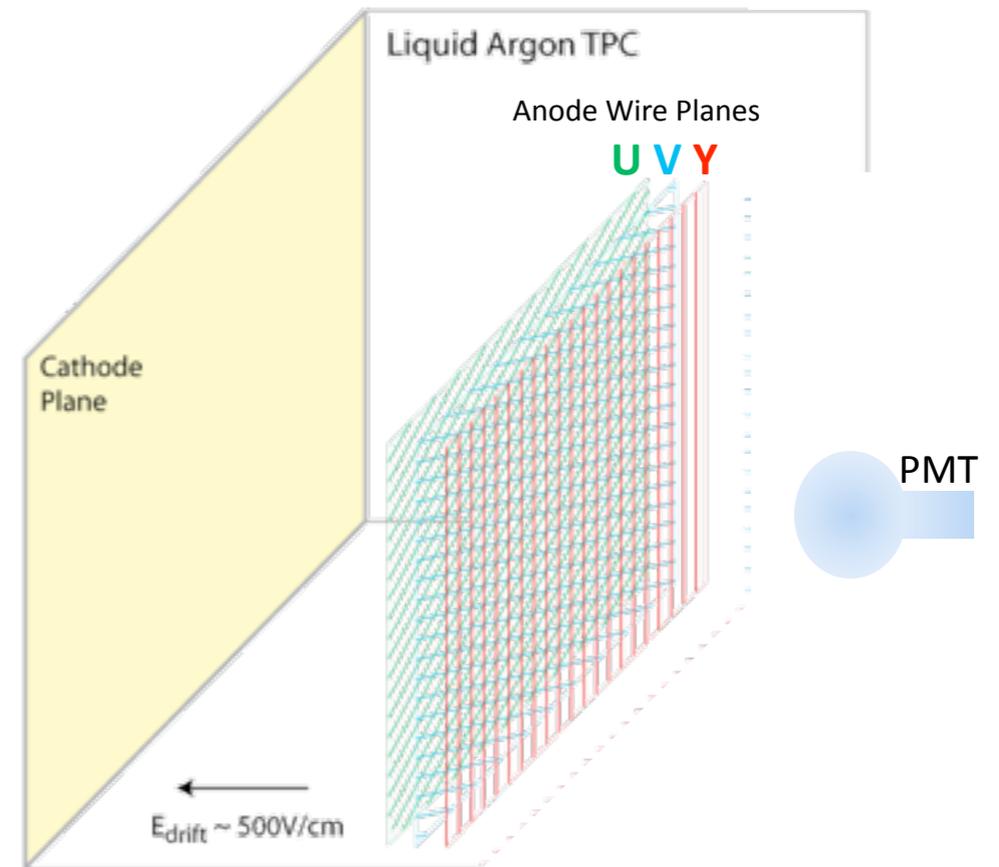

Figure 3.7: The graph shows the behaviour of the luminescence light intensity and of the collected charge as function of the electric field strength. The y axis scales

LAr Purity

(Electro-negative impurities diminish (eat) our signal; Nitrogen quenches scintillation light)

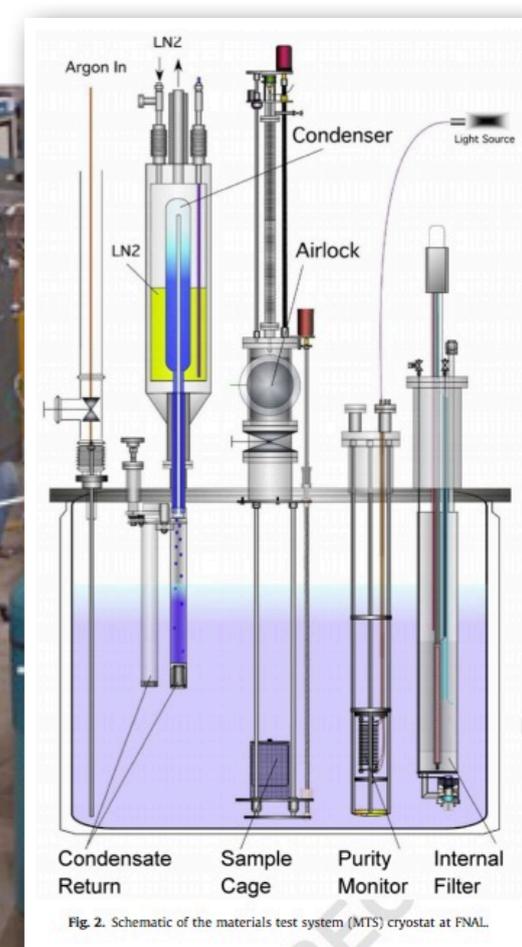

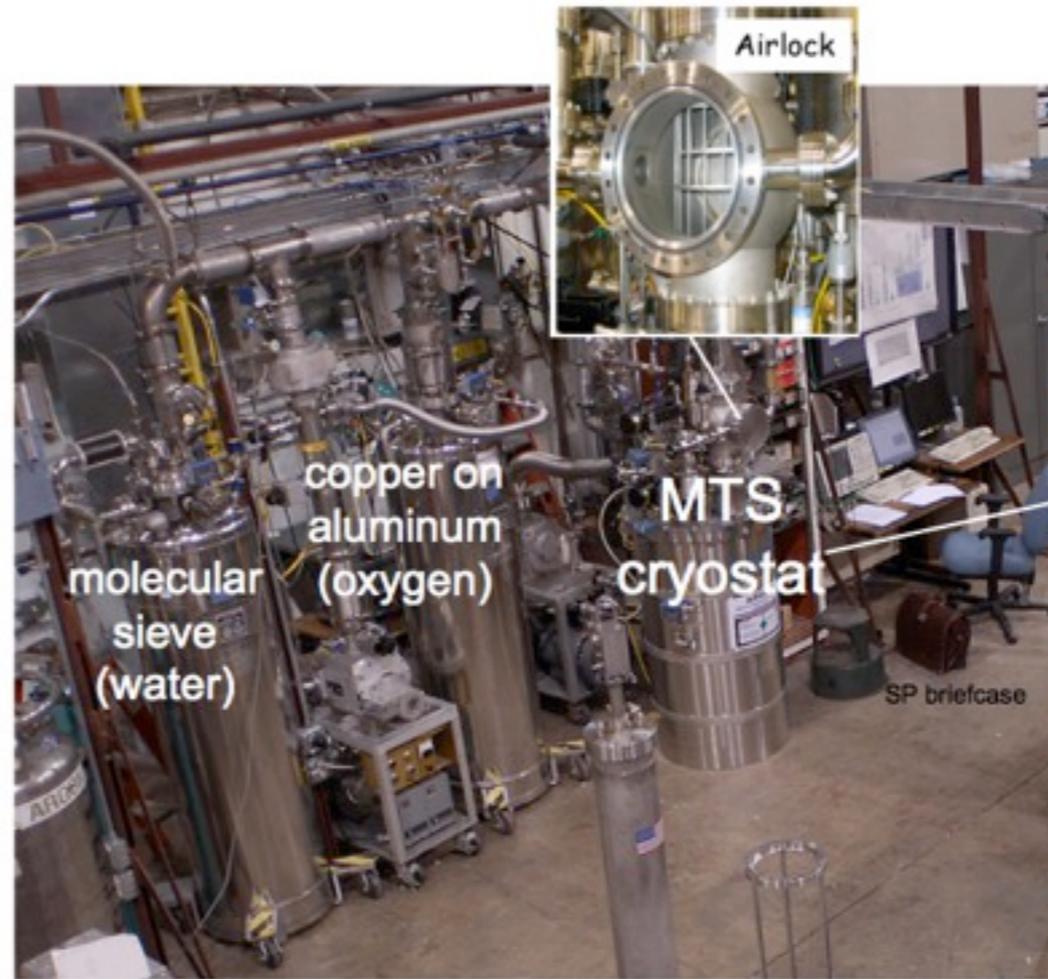

Purity

Purity

- Typical requirements are ~ 100 ppt O₂ and < 1 ppm N₂
 - O₂ is electronegative -- captures signal electrons
 - N₂ quenches light

Purity

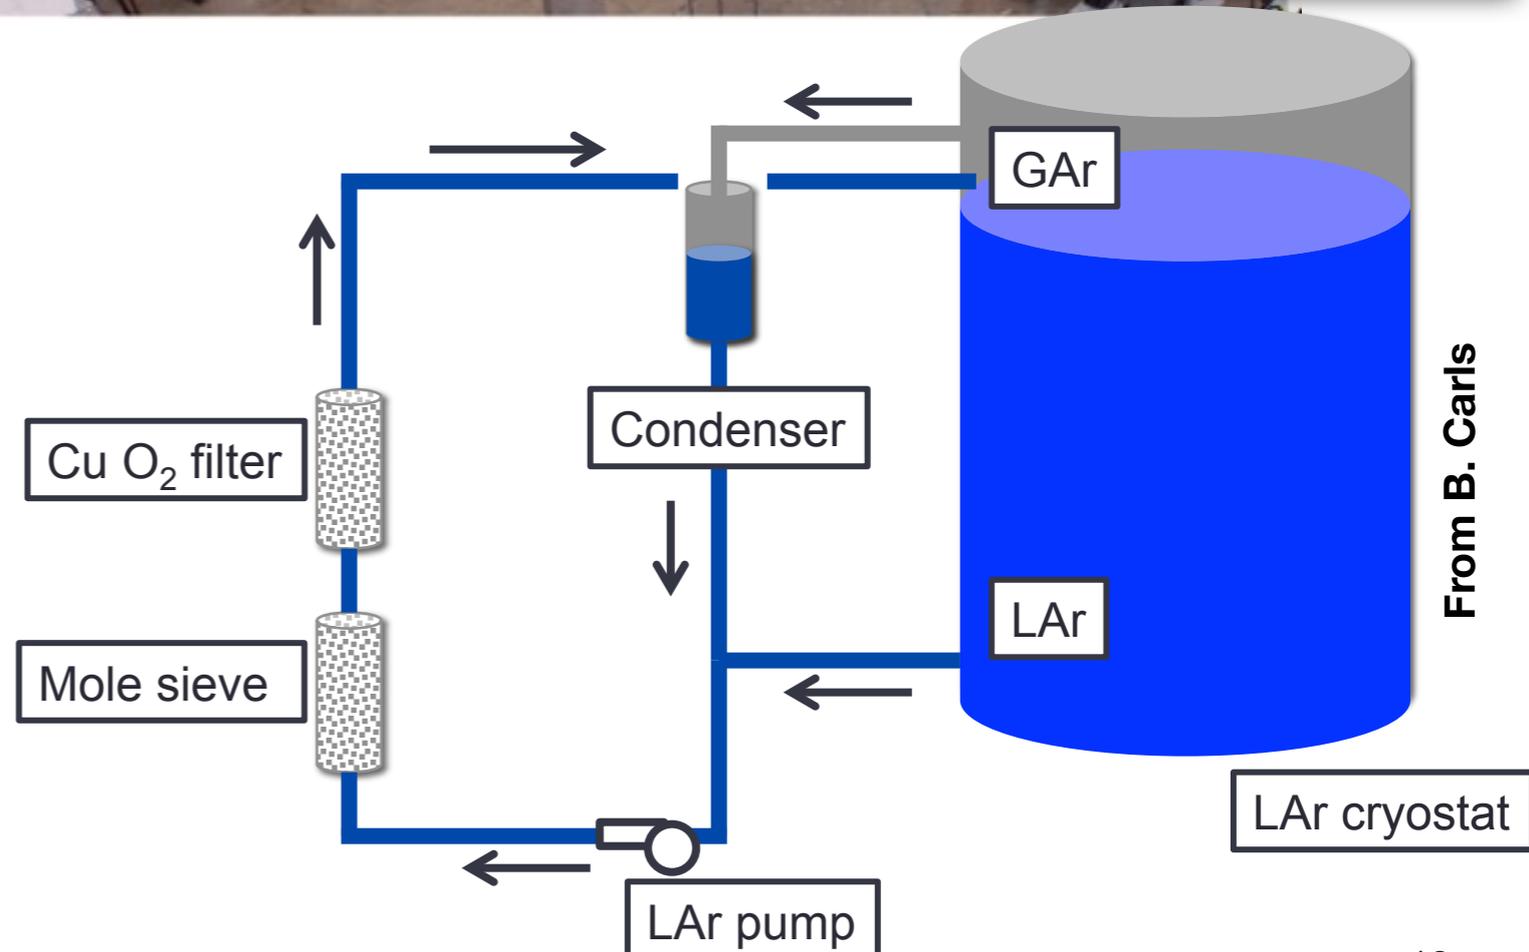

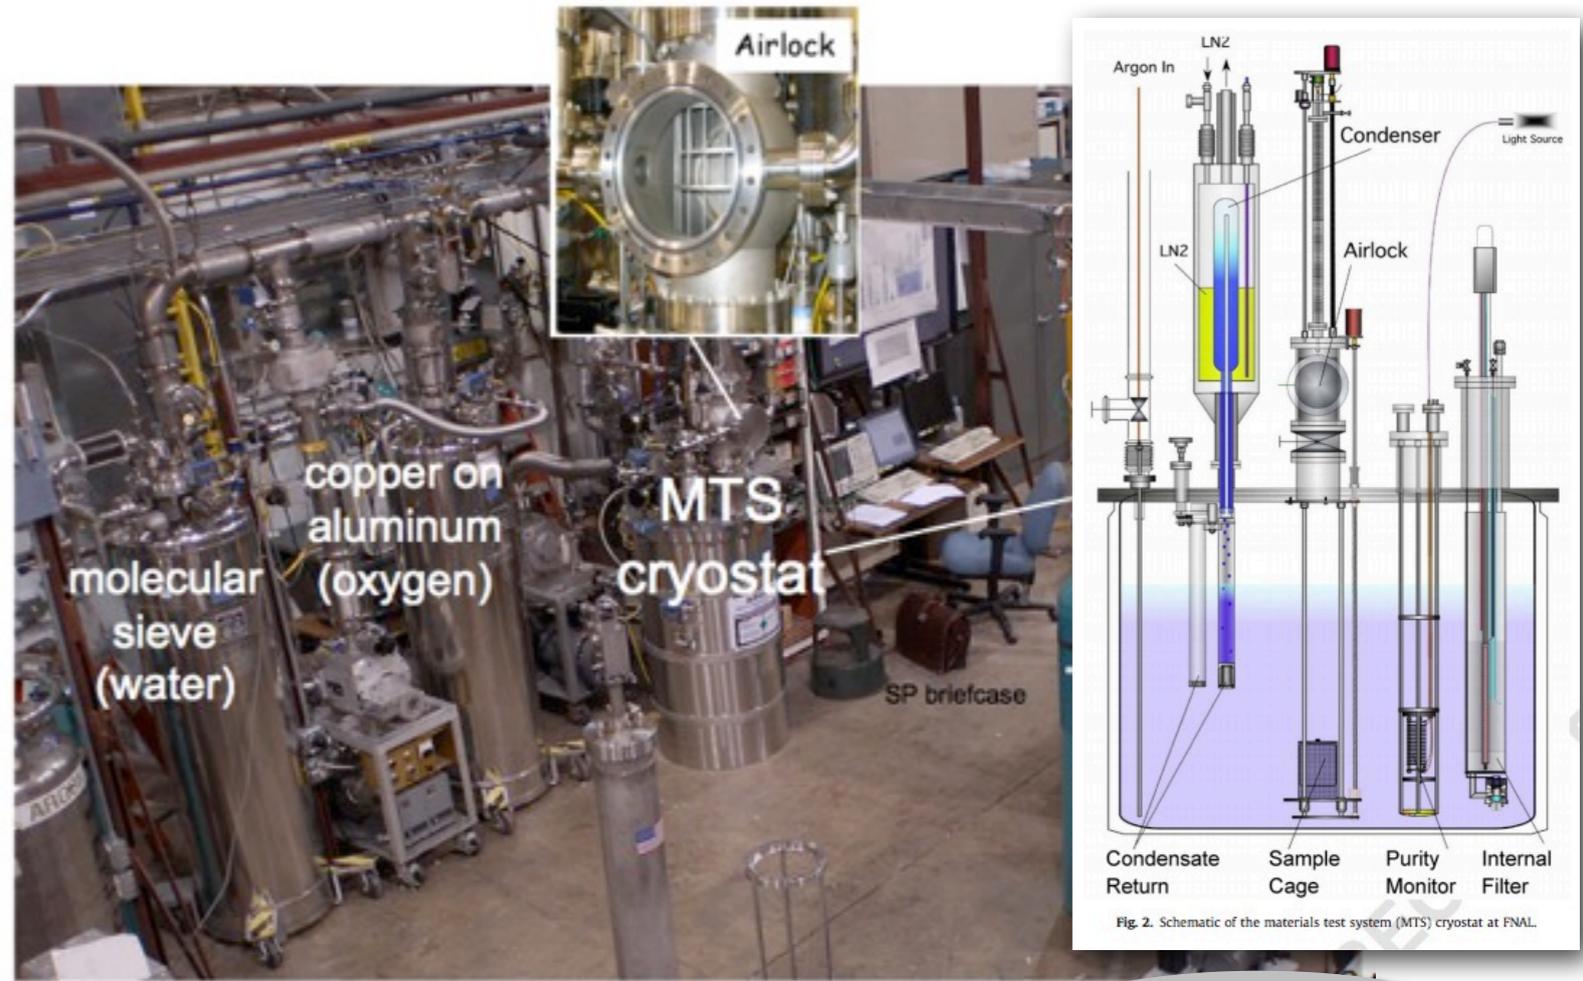

- Typical requirements are ~ 100 ppt O₂ and < 1 ppm N₂
 - O₂ is electronegative -- captures signal electrons
 - N₂ quenches light
- Materials are tested at the Materials Test Stand at PAB before going into a cryostat
 - We don't want anything to "poison" the argon; outgassing in the gas space can be bad

From B. Carls

Purity

- Typical requirements are ~ 100 ppt O₂ and < 1 ppm N₂
 - O₂ is electronegative -- captures signal electrons
 - N₂ quenches light
- Materials are tested at the Materials Test Stand at PAB before going into a cryostat
 - We don't want anything to "poison" the argon; outgassing in the gas space can be bad
- We can purify the LAr with filters:

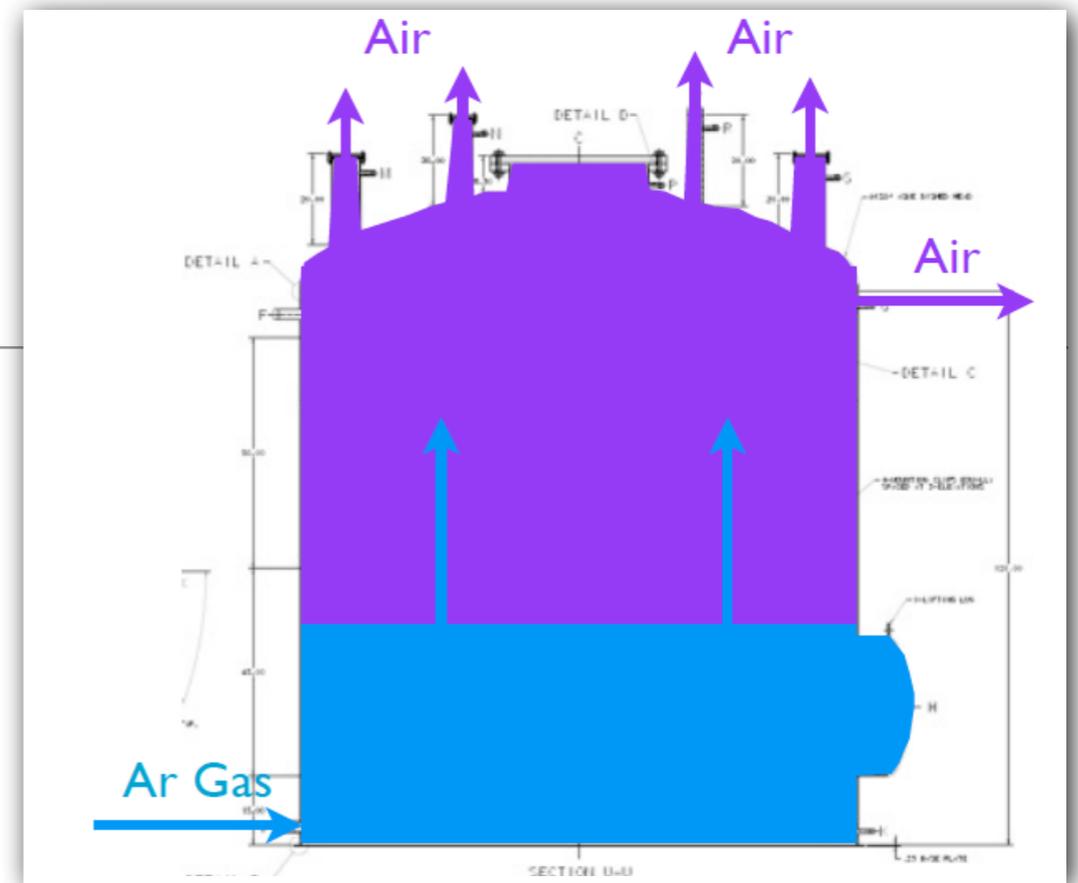

Purge

Purge

- Previous experiments evacuated their cryostat to get to the purity they need
 - ICARUS, Argoneut

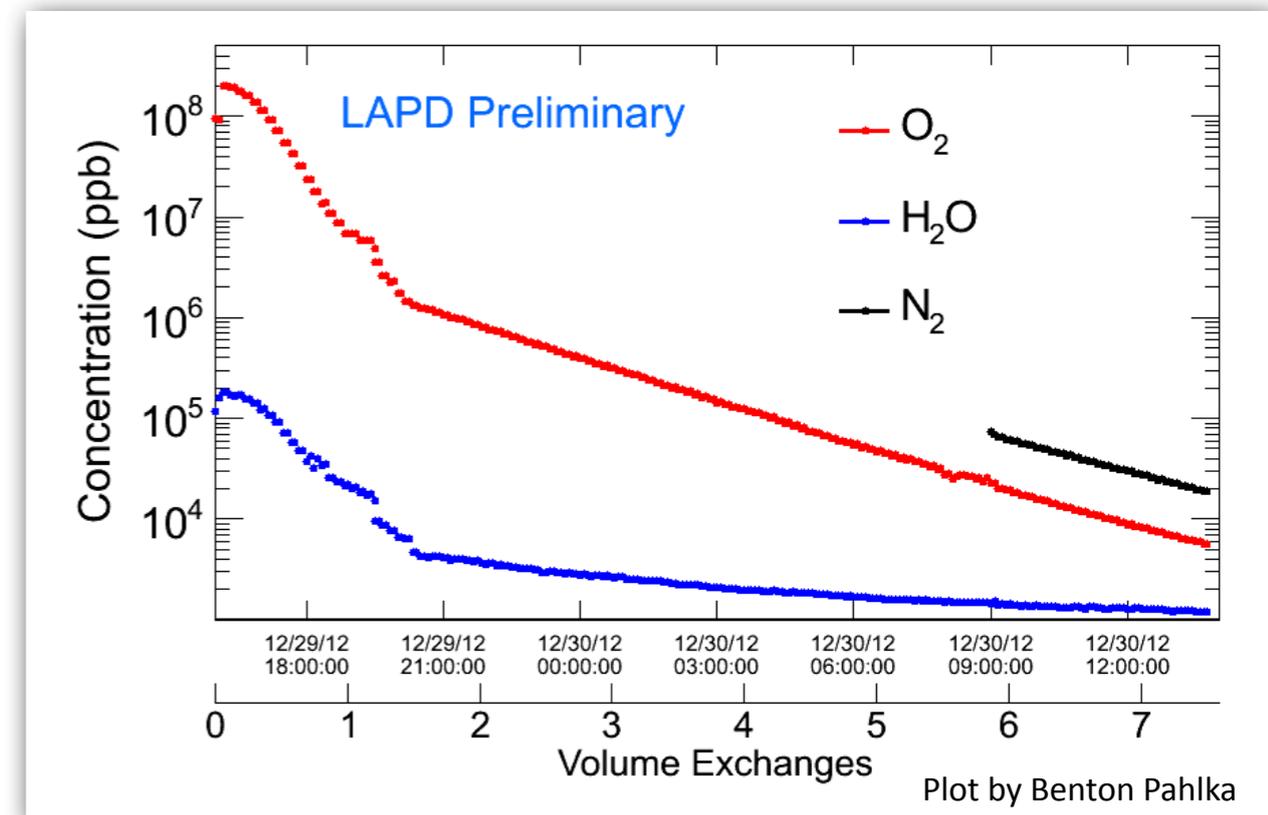

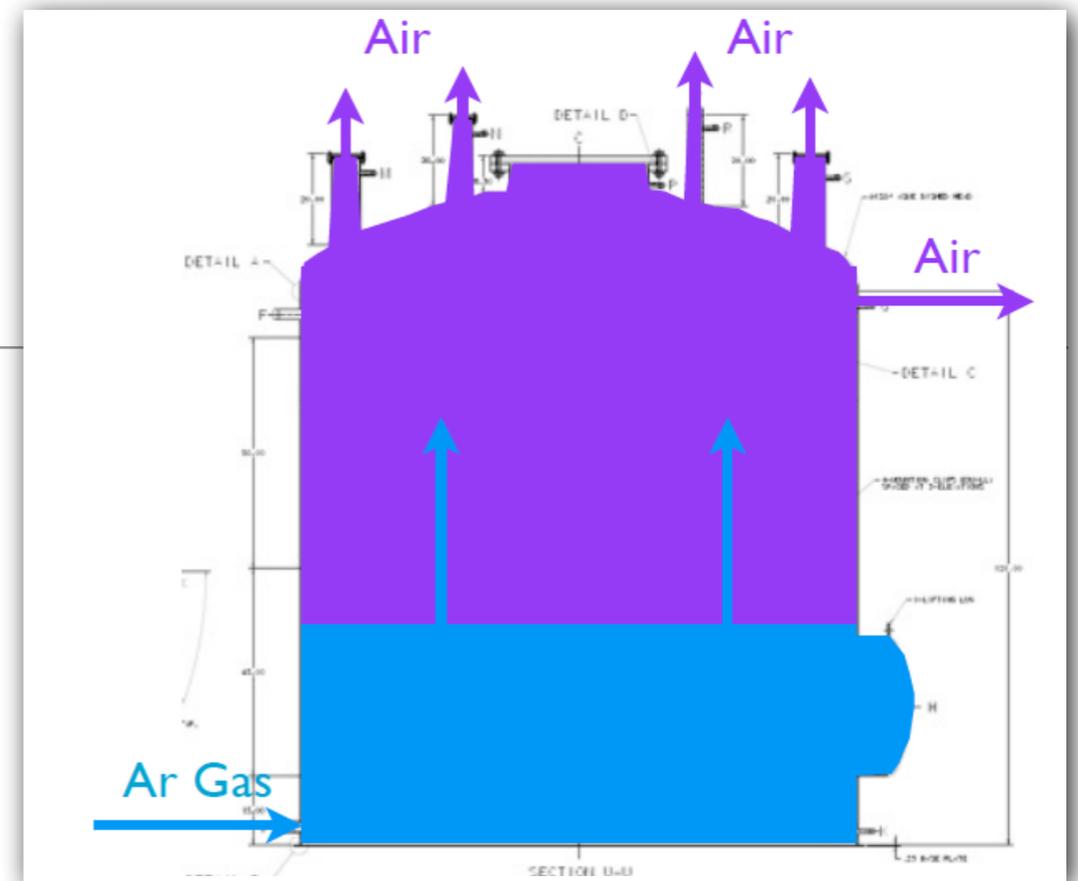

Purge

- Previous experiments evacuated their cryostat to get to the purity they need
 - ICARUS, Argoneut
- LAPD showed that purity requirements could be attained **without** the need for evacuating (~30 ton vessel)
 - They employed an argon-gas piston

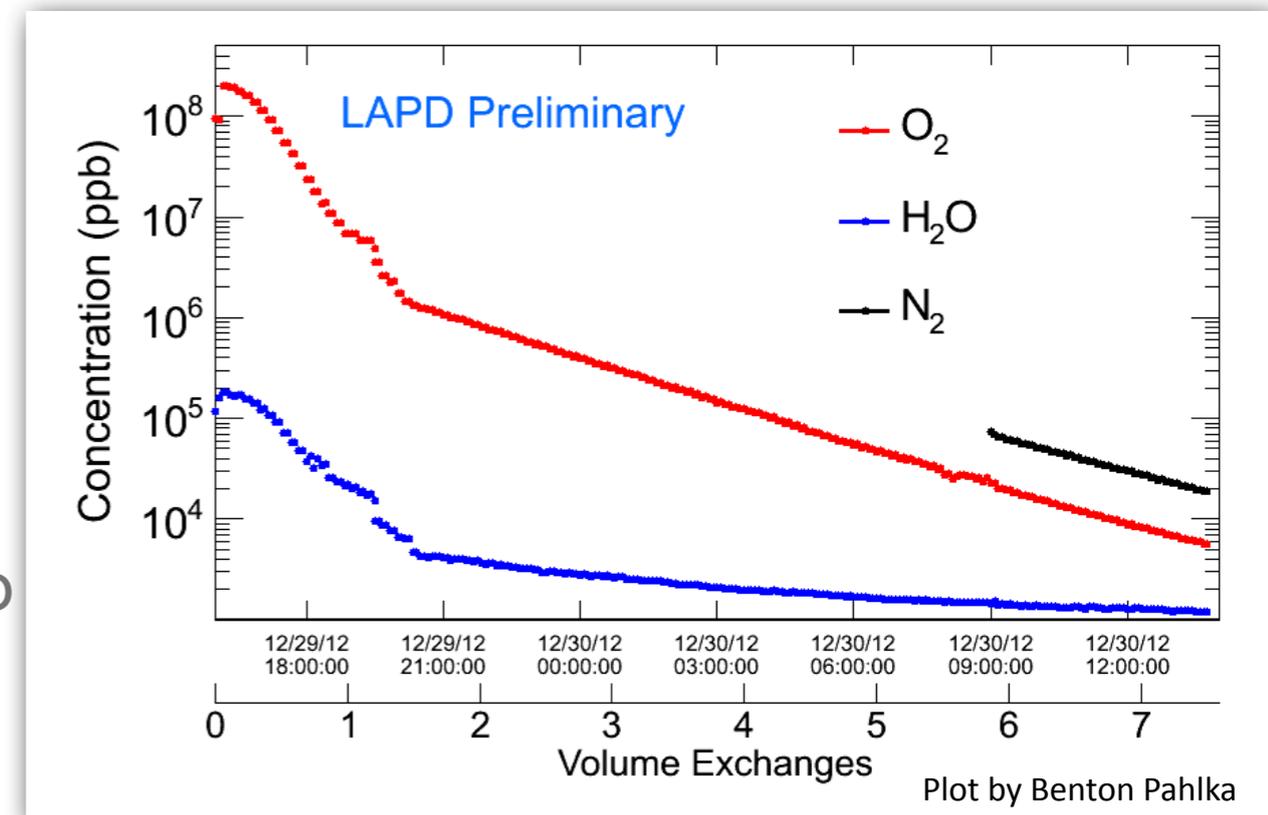

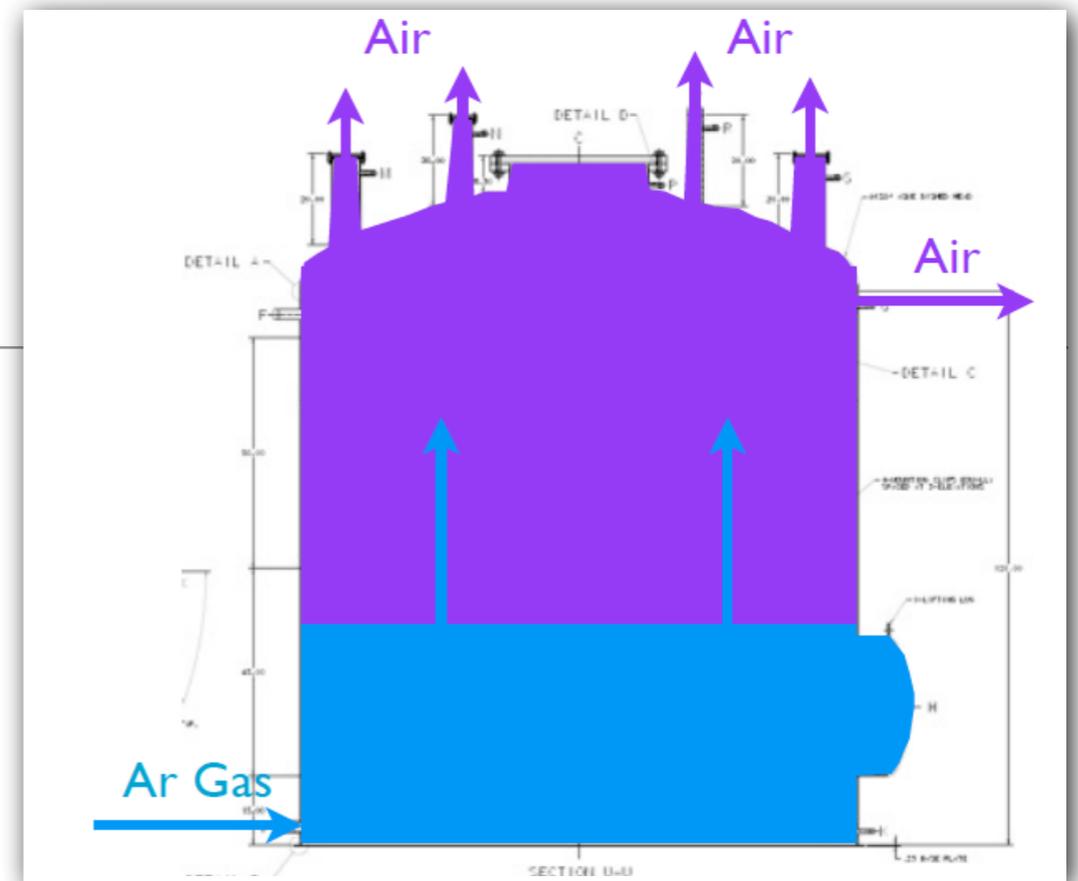

Purge

- Previous experiments evacuated their cryostat to get to the purity they need
 - ICARUS, Argoneut
- LAPD showed that purity requirements could be attained **without** the need for evacuating (~30 ton vessel)
 - They employed an argon-gas piston
 - O₂: 21% to 6 ppm
 - N₂: 78% to 18 ppm
 - H₂O: 200 ppm to 1.2 ppm

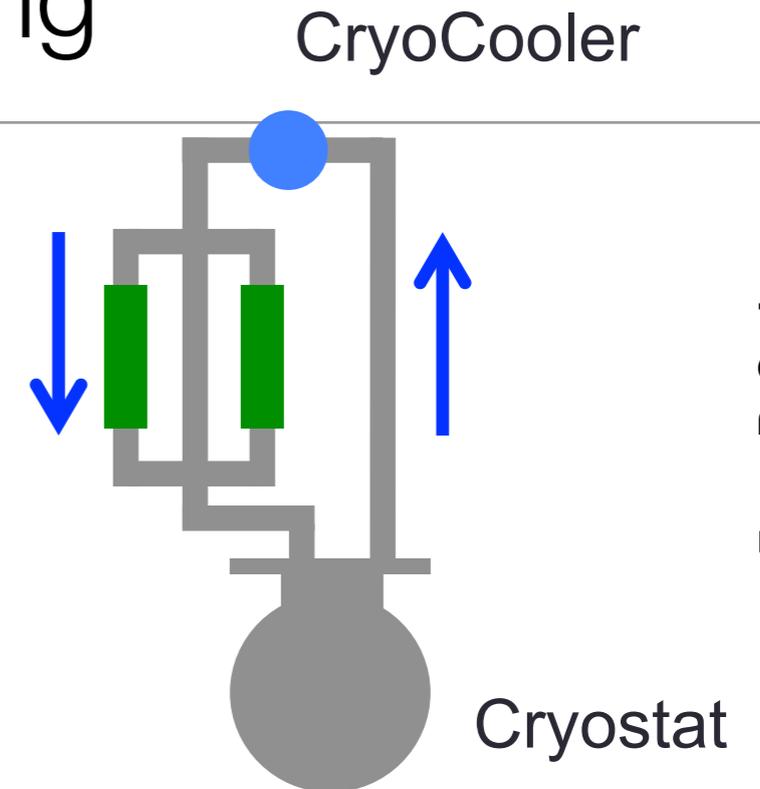

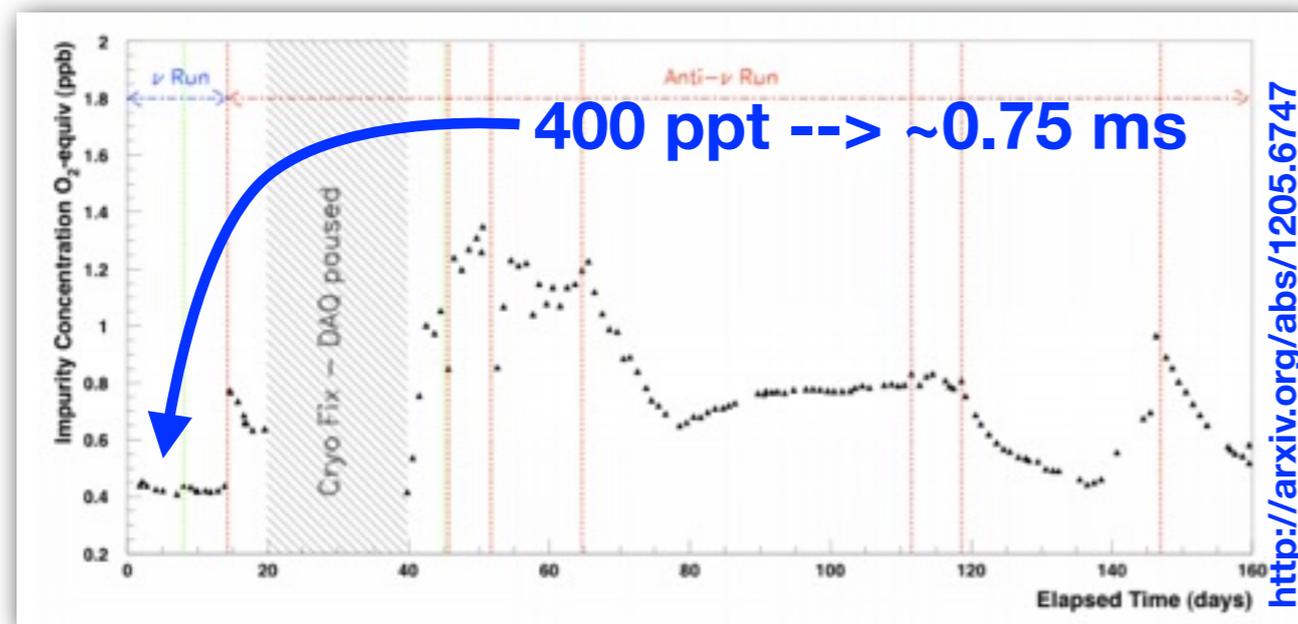

Purge

- Previous experiments evacuated their cryostat to get to the purity they need
 - ICARUS, Argoneut
- LAPD showed that purity requirements could be attained **without** the need for evacuating (~30 ton vessel)
 - They employed an argon-gas piston
 - O₂: 21% to 6 ppm
 - N₂: 78% to 18 ppm
 - H₂O: 200 ppm to 1.2 ppm
- This is important because it costs \$\$\$ to make a cryostat that can be evacuated

More Comments on Purity & Purging

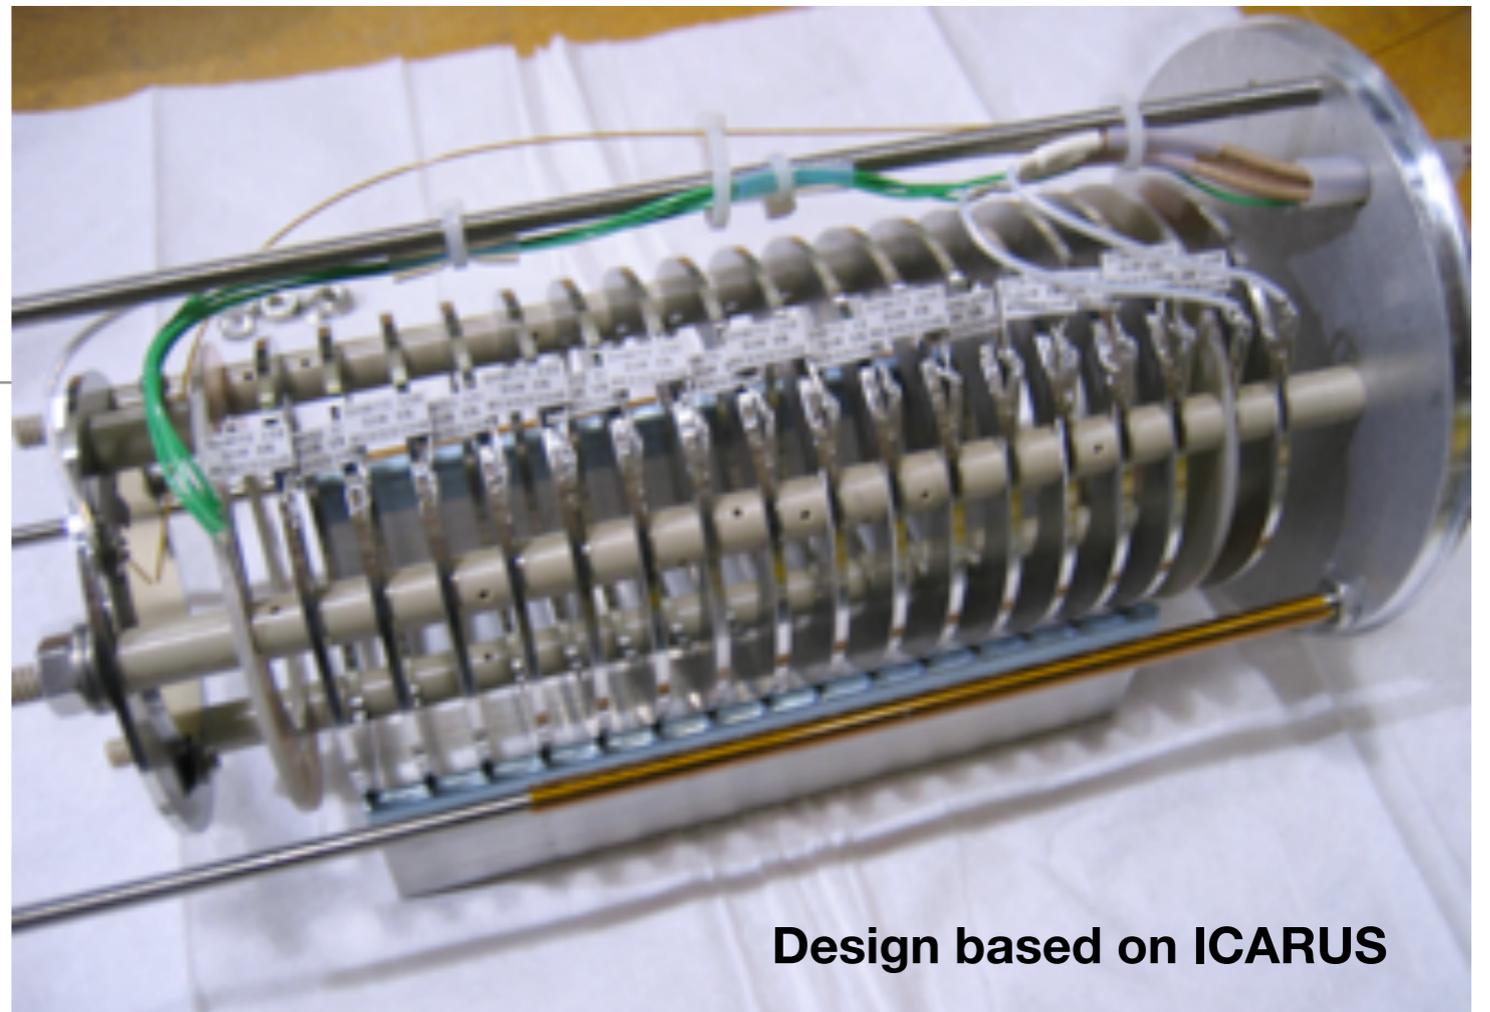

- Even though Argoneut evacuated, their purity could have been improved upon
 - The system condensed argon from the gas space (good -- a lot of impurities live here) and filtered it
 - But a faster filtration rate (pumps) would lead to better purity
- Lesson -- evacuation is not a cure all!

Monitoring Purity

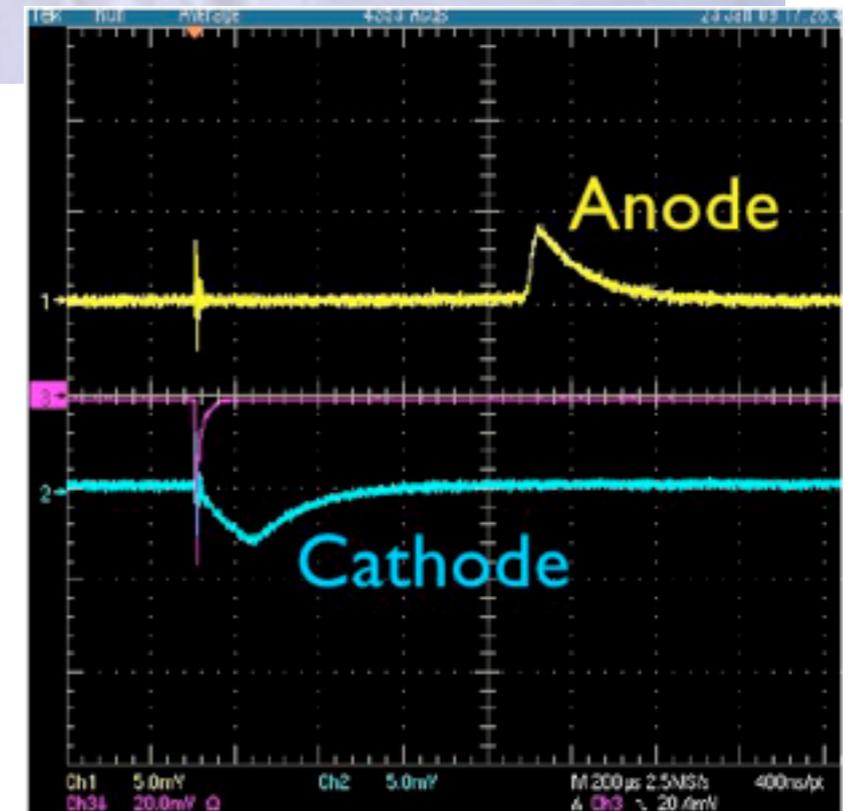

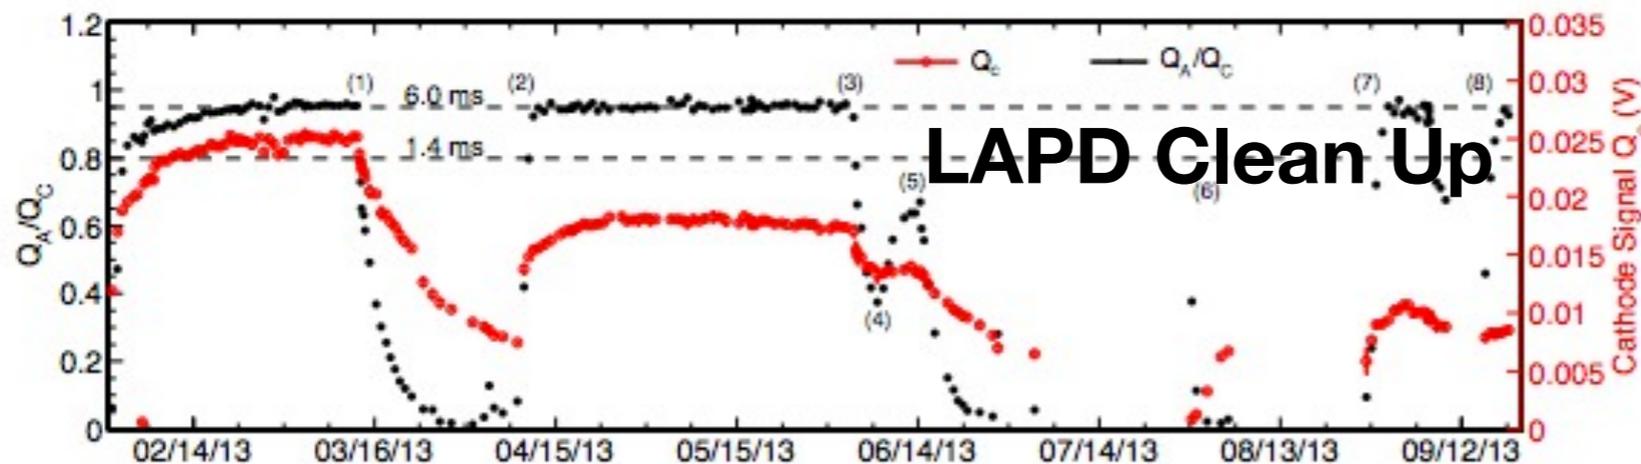

- Purity monitors placed in the tank and in the cryosystem will give attenuation measurements
 - Use a xenon flash lamp on a photocathode
 - Cathode signal is Q_0 , anode is Q

$$\frac{Q_0}{Q} = e^{t_d/\tau}$$

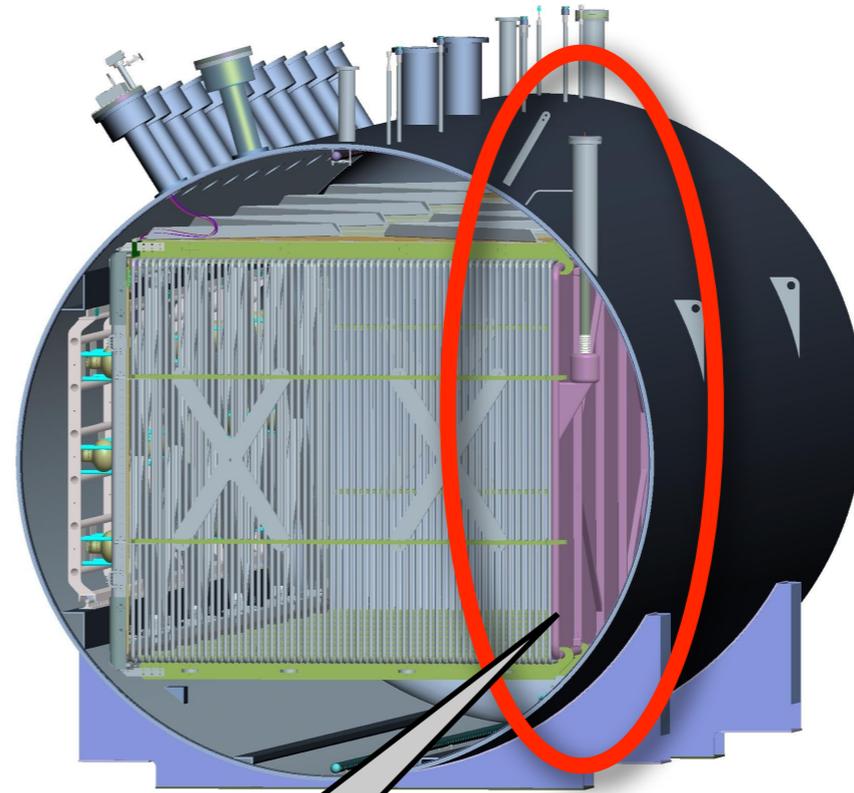

Design based on ICARUS

It's like a little TPC...

Cathode HV

This makes
the E Field

Cathode High Voltage

- Again, a high voltage on the cathode supplies the drift field
 - A Cockcroft-Walton/Greinacher system generates the HV **inside** of the cryostat
- ARGONTUBE at Bern uses this
 - 5 m drift
 - Able to get to 125 kV (stable; $E = 250$ V/cm); 150 kV max

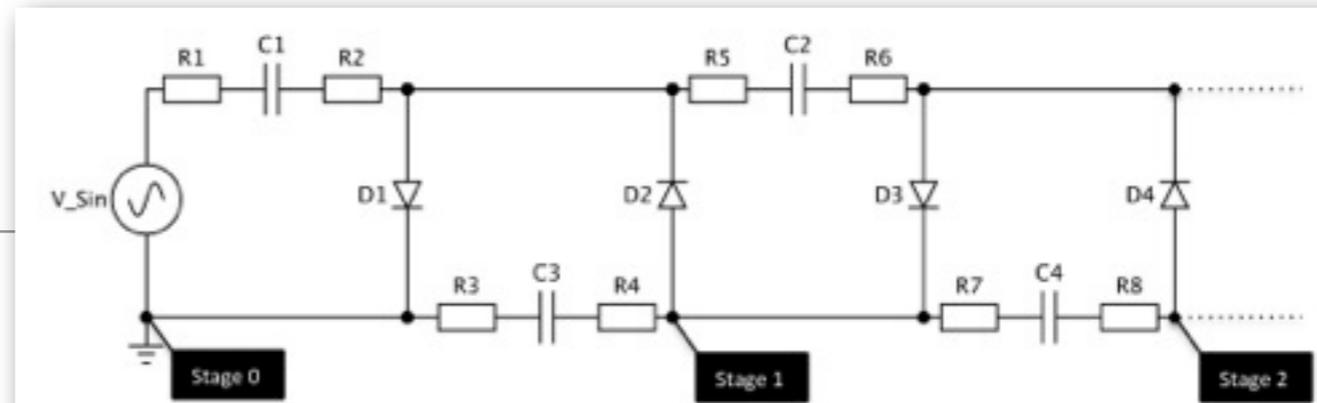

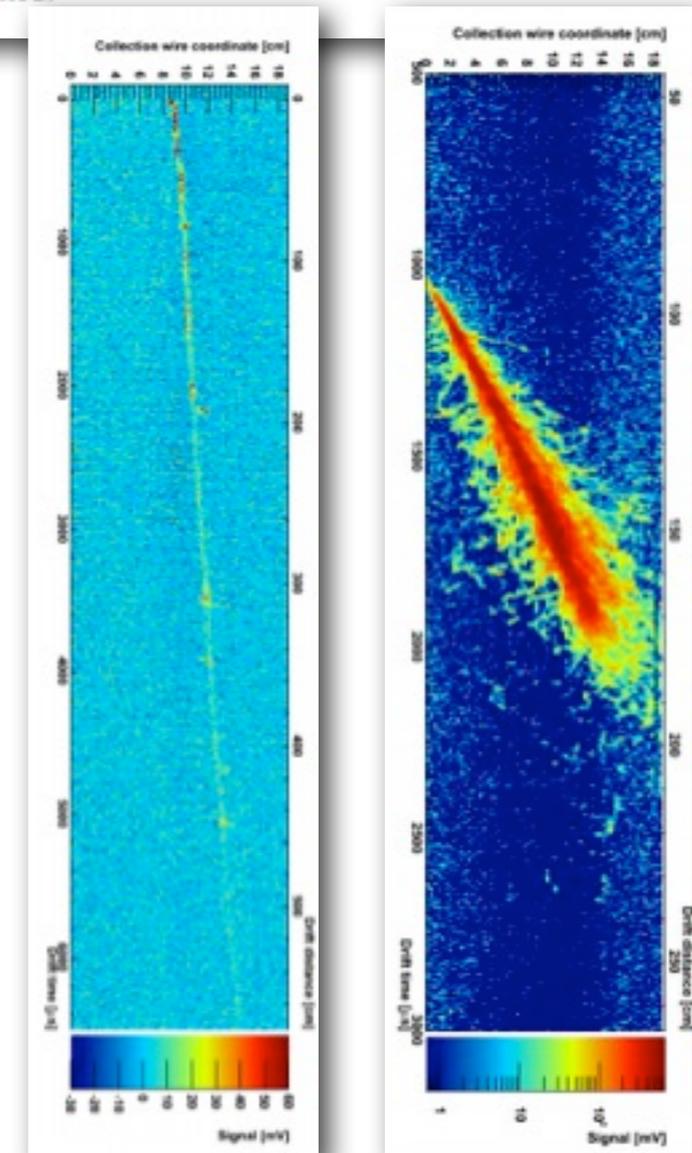

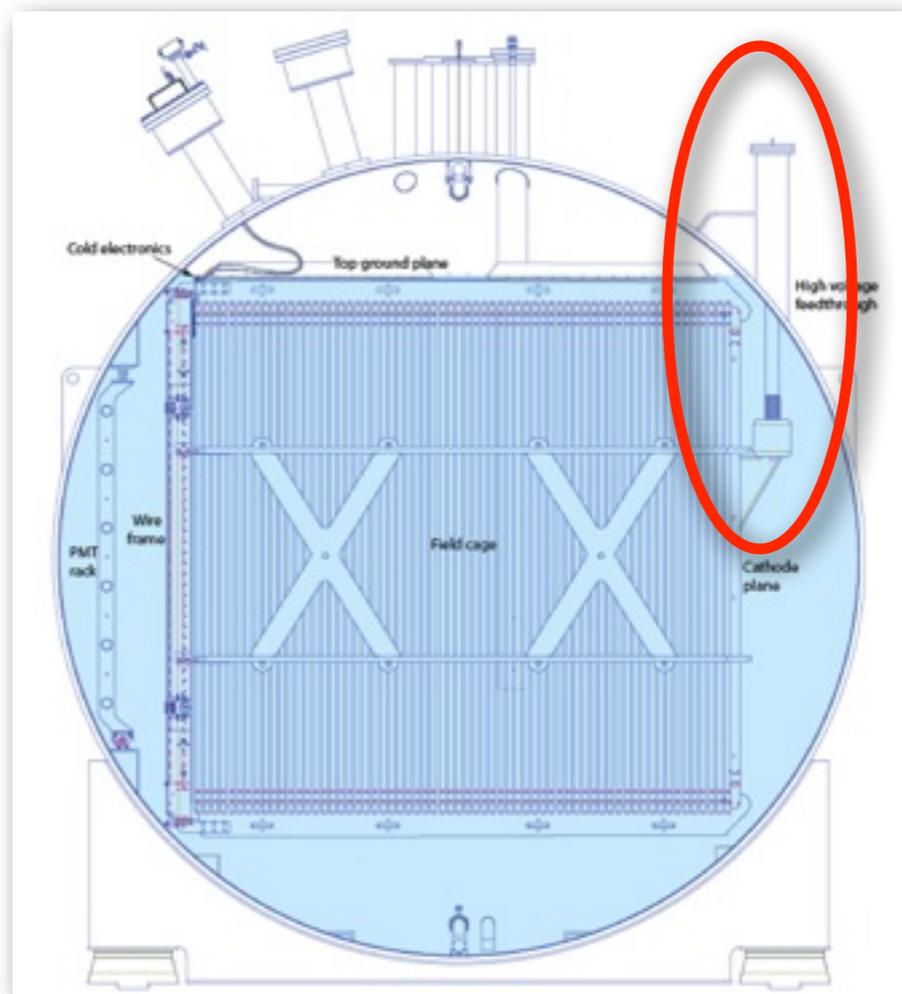

Figure 6. Wiring diagram of the Greinacher circuit for negative high voltage. Two stages of this circuit are shown, in ARGONTUBE 125 stages are mounted.

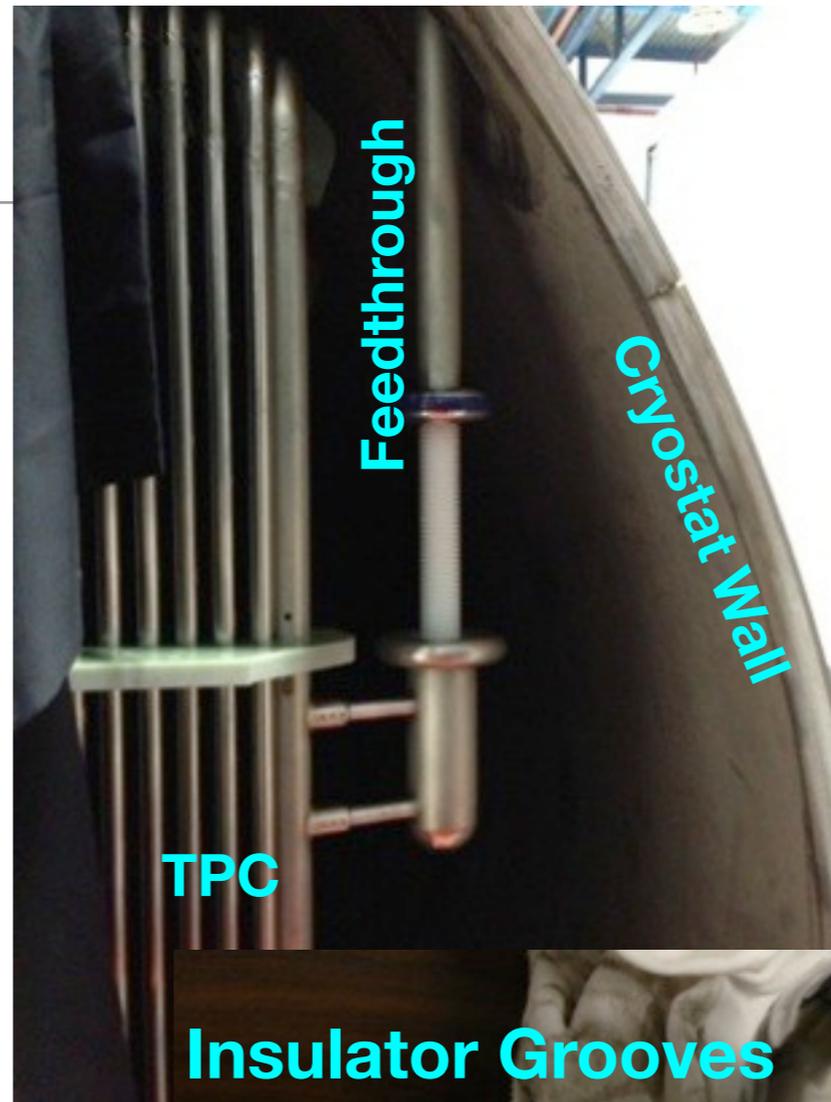

Cathode High Voltage

- Or the high voltage can be made **outside** of the cryostat and connected to the cathode via an HV **feedthrough**
- This is what MicroBooNE (among others) uses
- Can buy supplies (-150 kV Glassman)
- Have to make the feedthrough

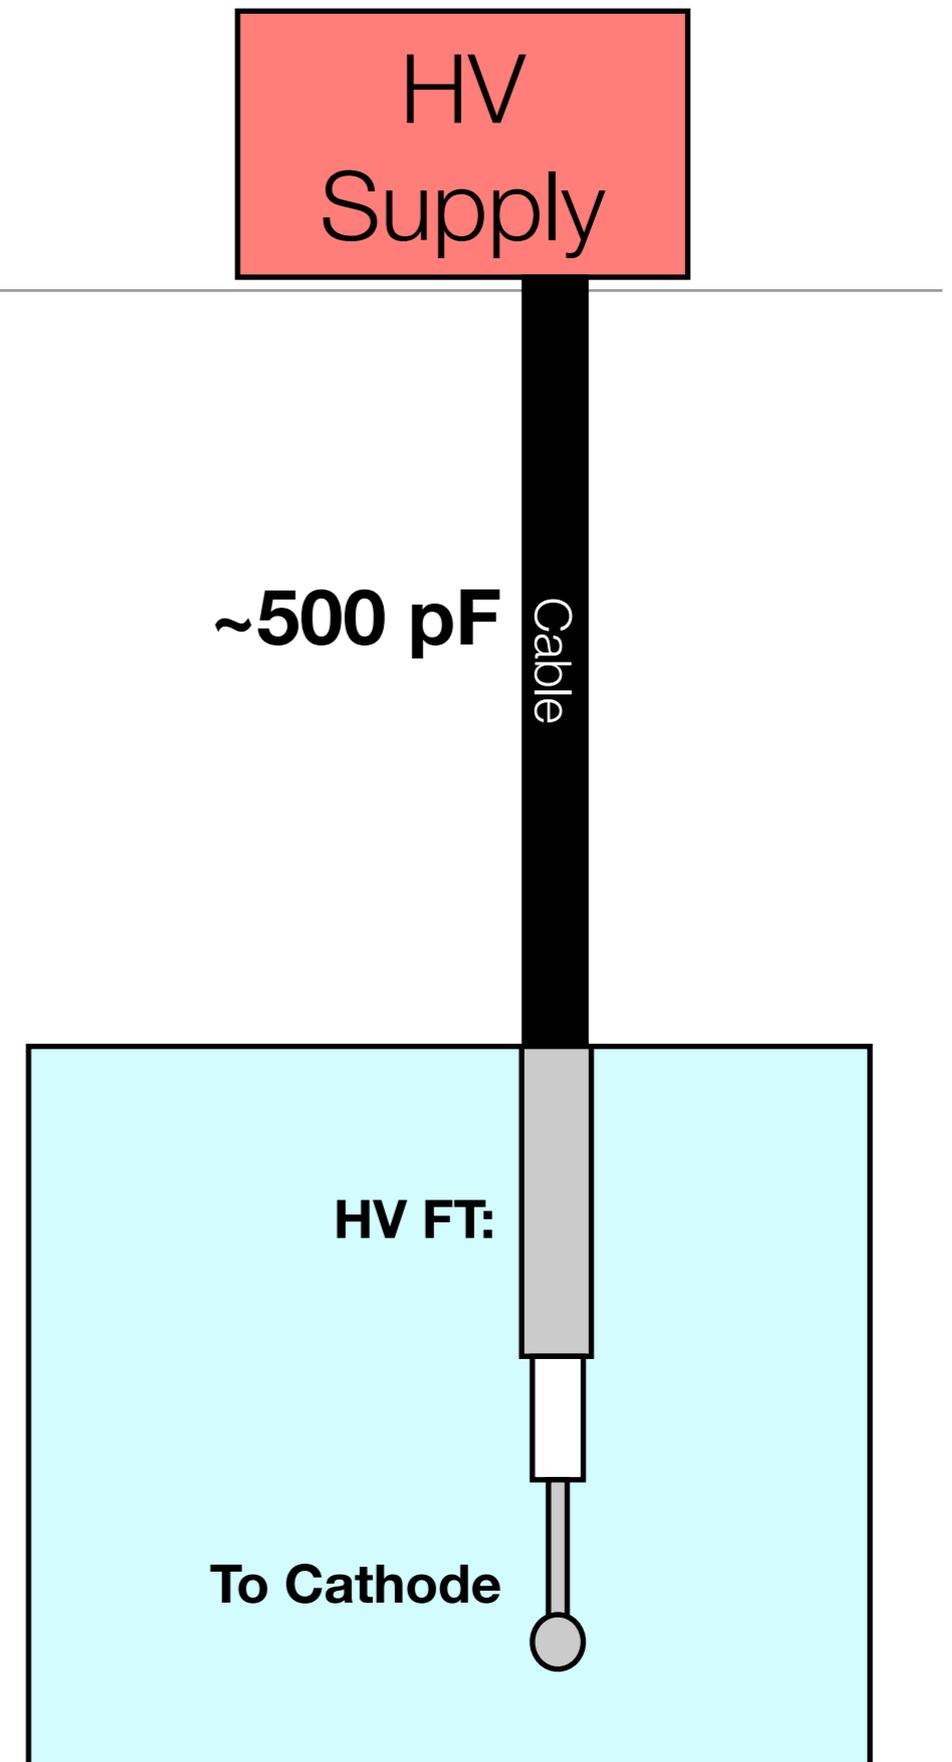

Feedthrough

- Needs to take 100+ kV into a cryostat
 - Maintain a good seal from room temperature to 87 K
- Inner stainless steel conductor
- Inserted into UHMW PE insulator
- Outer ground tube is cryo-fit over
 - Flange/warm part makes a tight seal

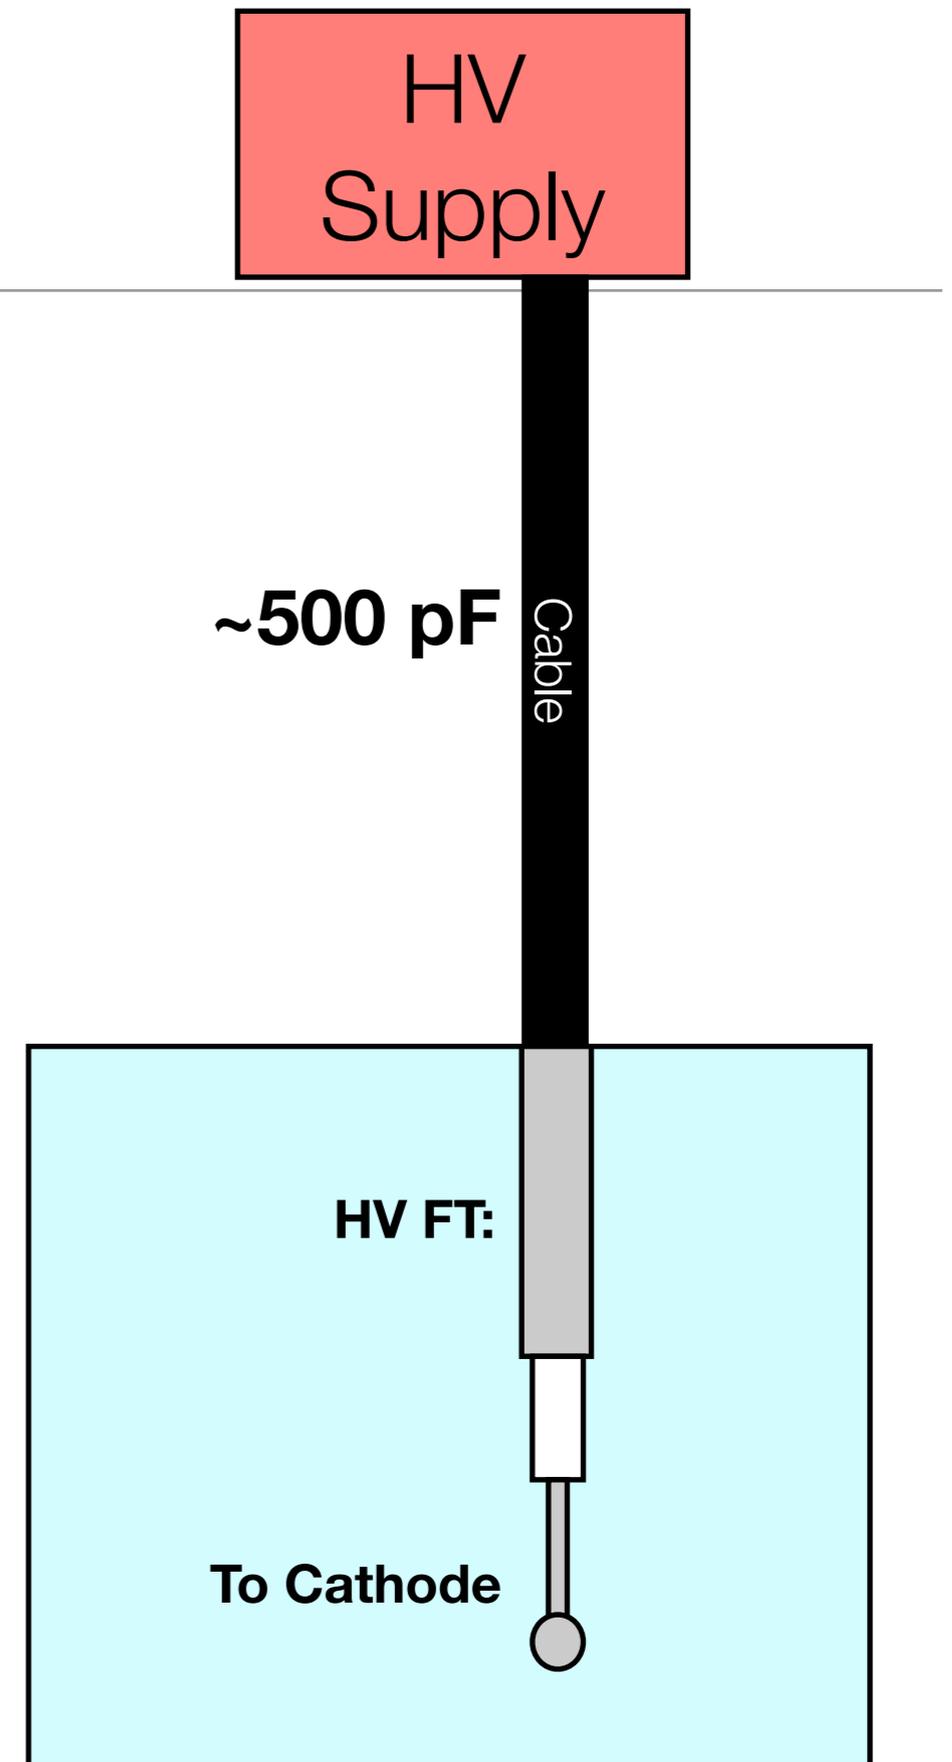

HV an Aside

HV an Aside

- There's a lot of energy stored upstream of the FT
- If there was a discharge, this could put a lot of energy into the TPC

HV an Aside

- There's a lot of energy stored upstream of the FT
- If there was a discharge, this could put a lot of energy into the TPC
- So we isolate the system by putting a filter pot in between

HV
Supply

500

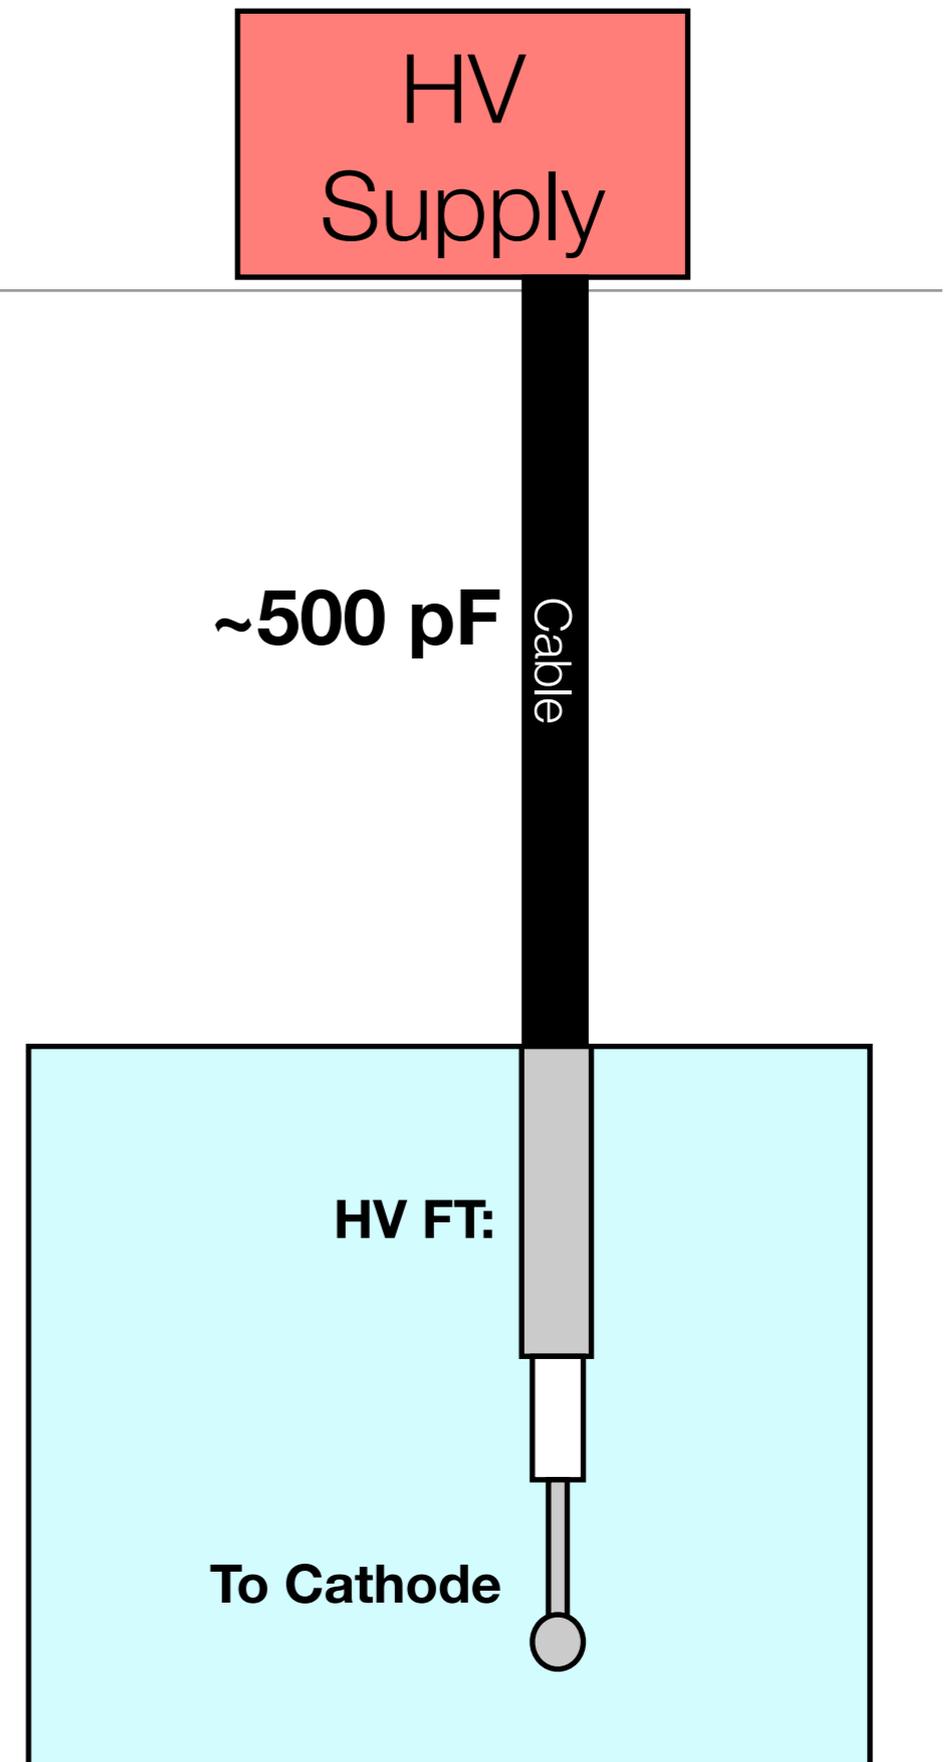

HV FT:

To Cathode

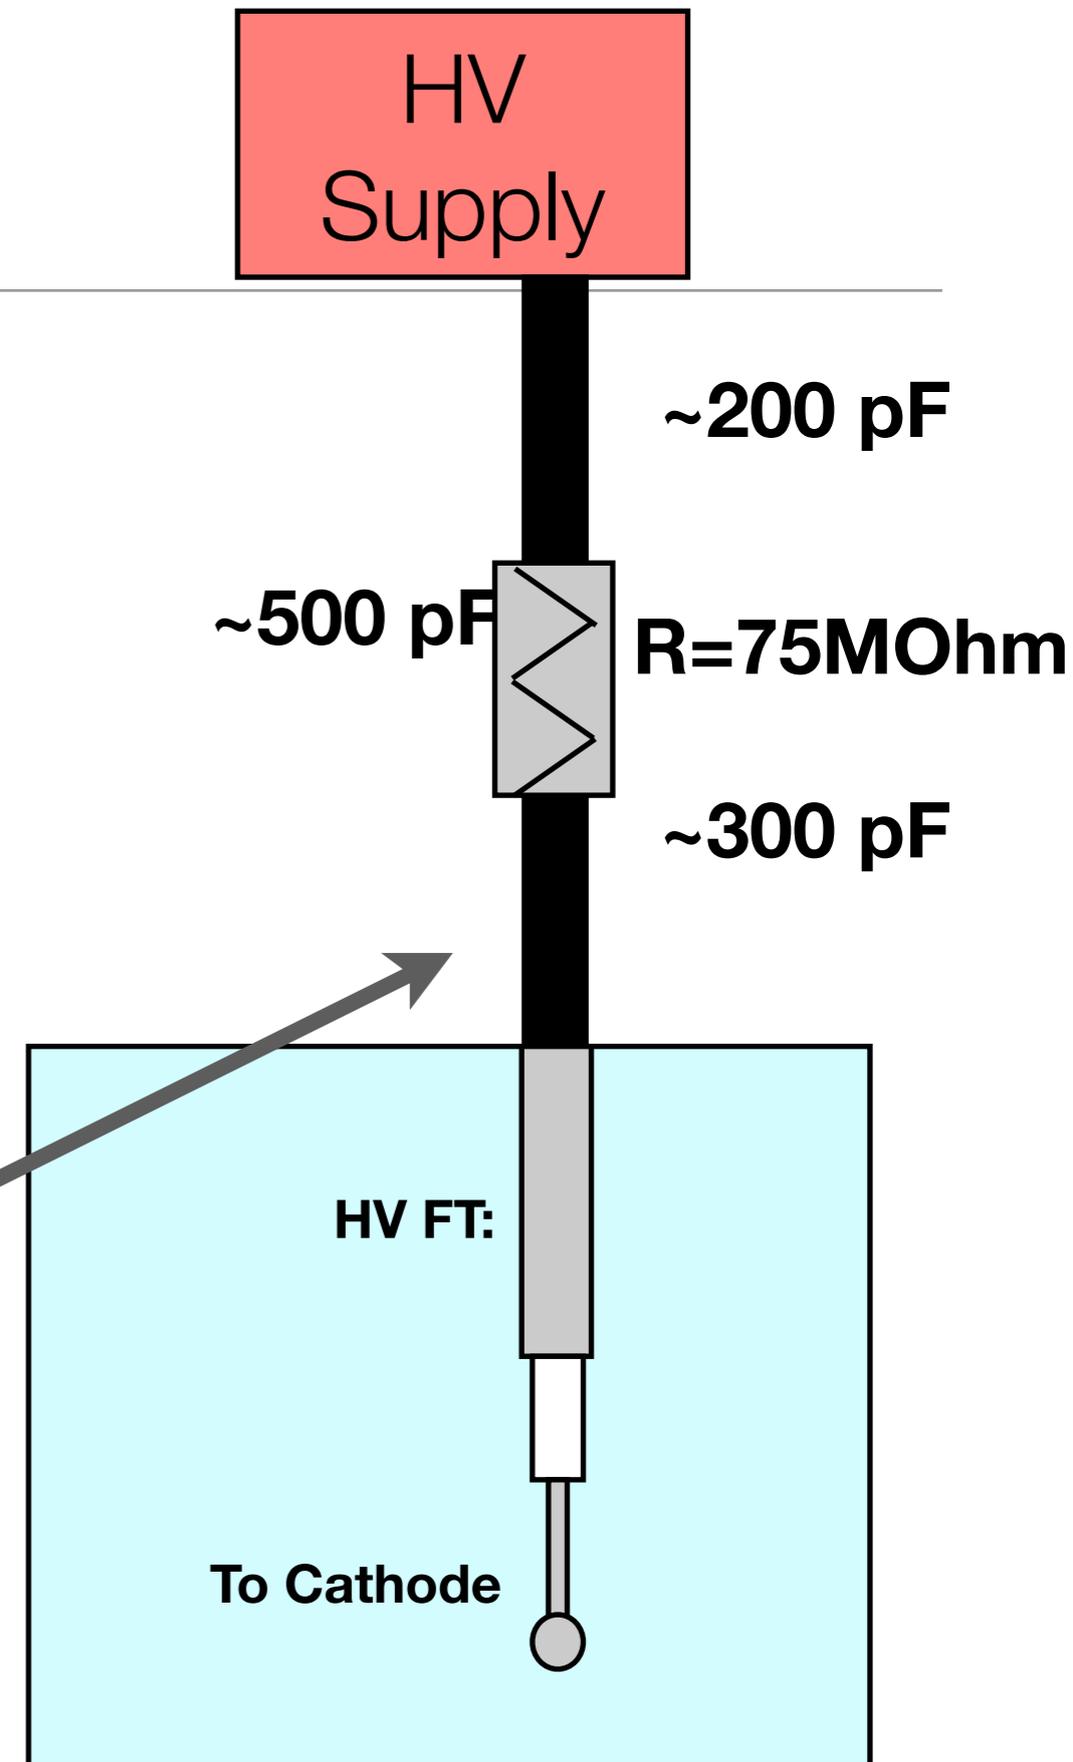

HV an Aside

- There's a lot of energy stored upstream of the FT
- If there was a discharge, this could put a lot of energy into the TPC
- So we isolate the system by putting a filter pot in between

HV an Aside

- There's a lot of energy stored upstream of the FT
- If there was a discharge, this could put a lot of energy into the TPC
- So we isolate the system by putting a filter pot in between
 - "Filter" refers to this low pass filter
 - Only this part will **quickly** enter the cryostat.

Other Things Related to HV

Other Things Related to HV

- While testing the HV feedthrough, we had a bit of a surprise

TABLE 6.2

- We had a number of features in the MicroBooNE TPC we were worried about
 - Screw heads on the TPC tubes -- could these cause LAr breakdown?
- We did a test in air:

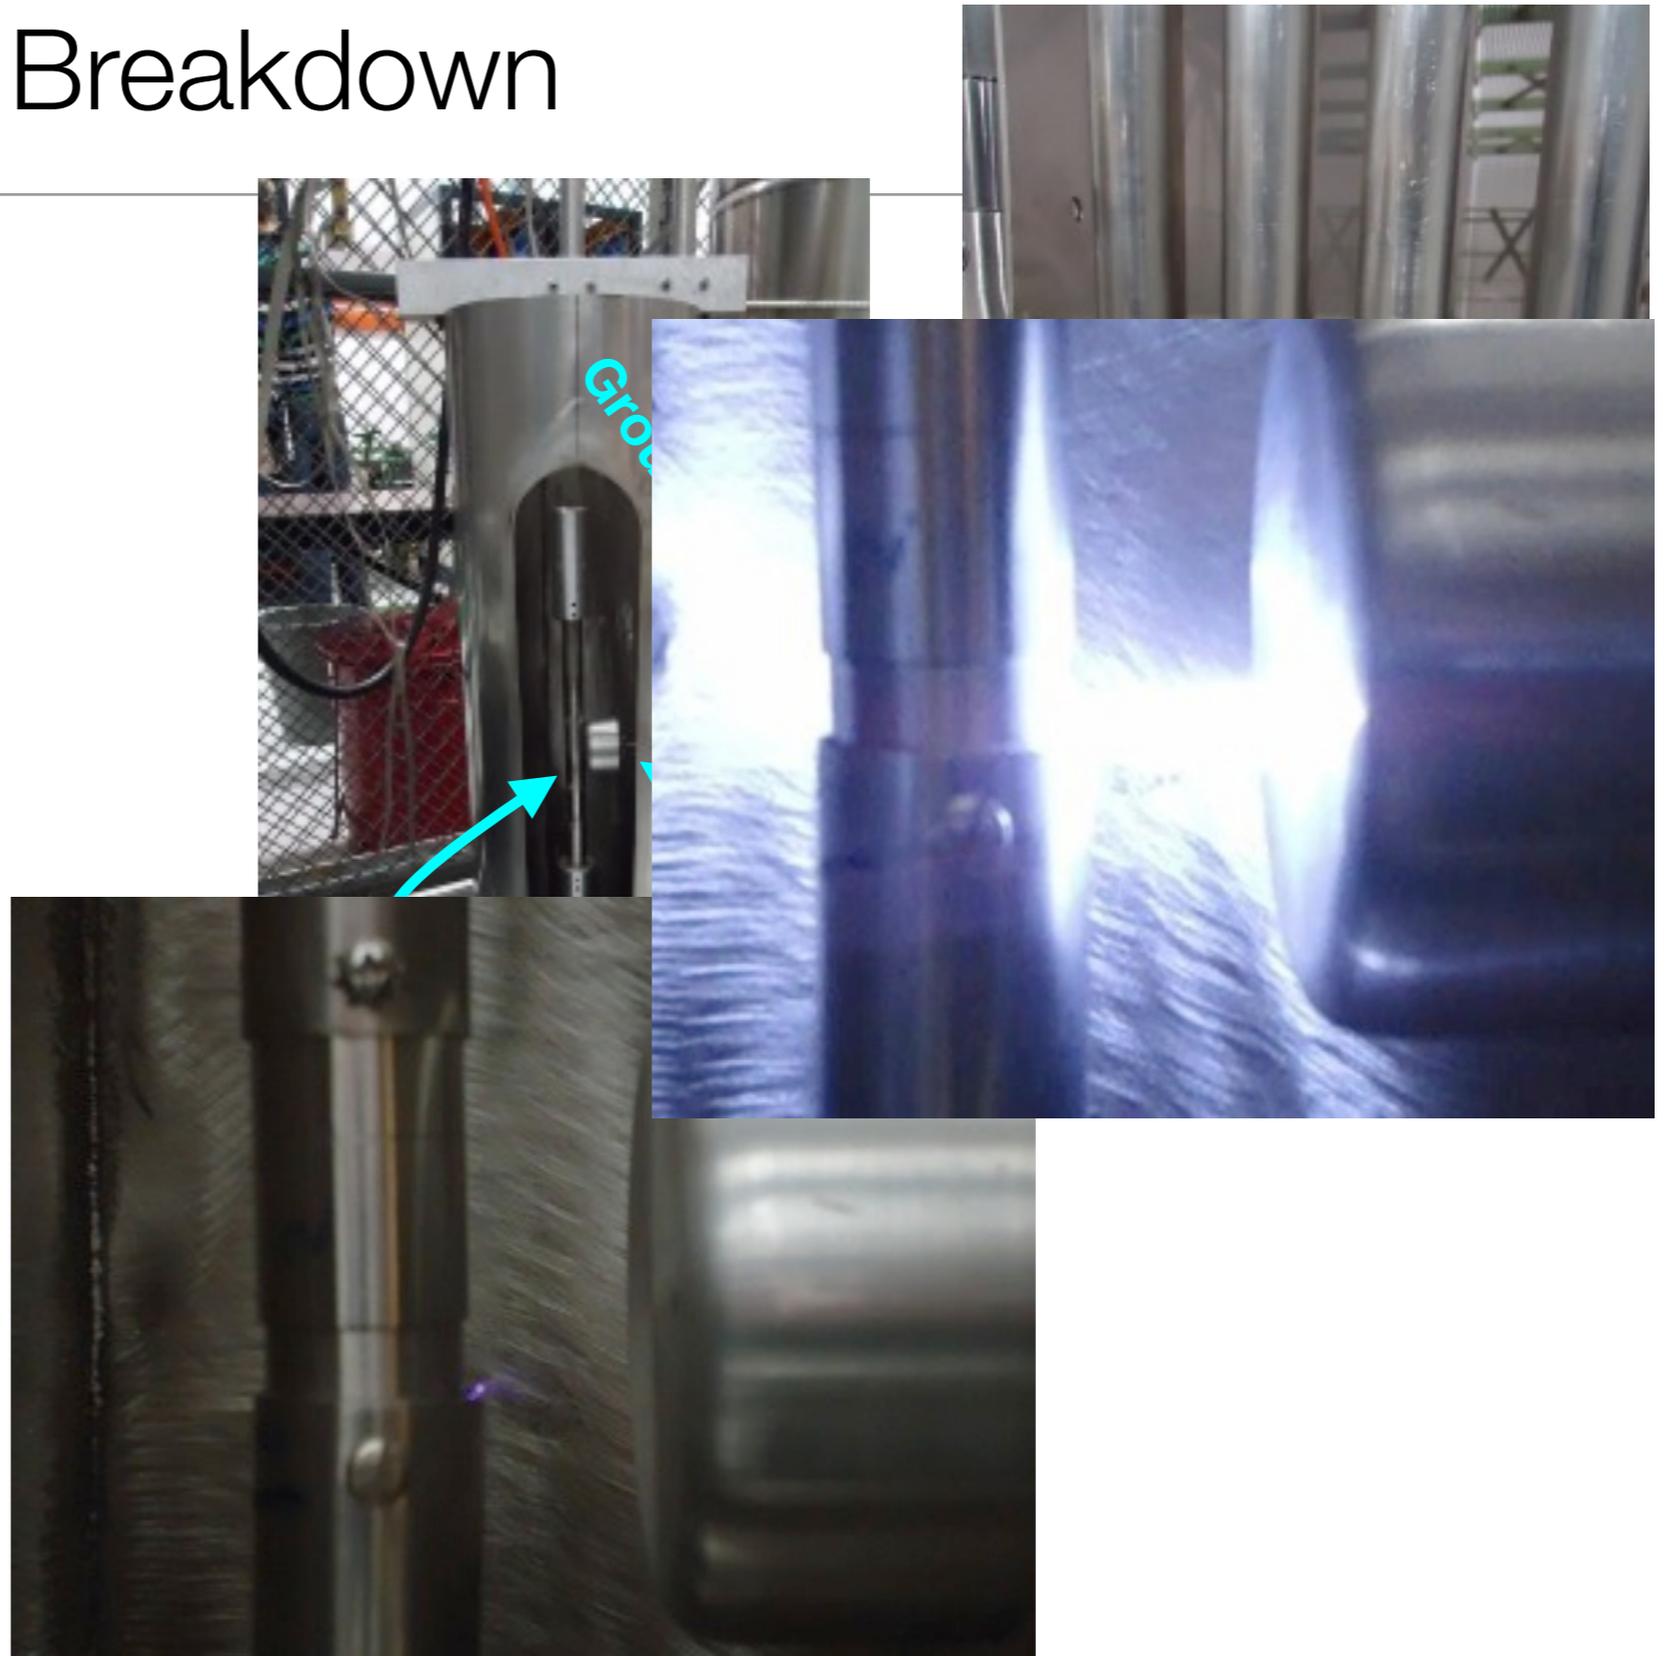

Testing Pieces for Breakdown

- We had a number of features in the MicroBooNE TPC we were worried about
 - Screw heads on the TPC tubes -- could these cause LAr breakdown?
- We did a test in air:
- We rotated all screw heads and modified some other pieces

Experiments

ICARUS

- Pioneer in the field
 - Proposed by C. Rubbia in 1977
- ICARUS T600
 - 2001 Pavia: 100 days on surface
 - 2010-2013 Gran Sasso: filled with 760 tons LAr (477 t)
 - 1.5 m drift; 75 kV on cathode

Experiments

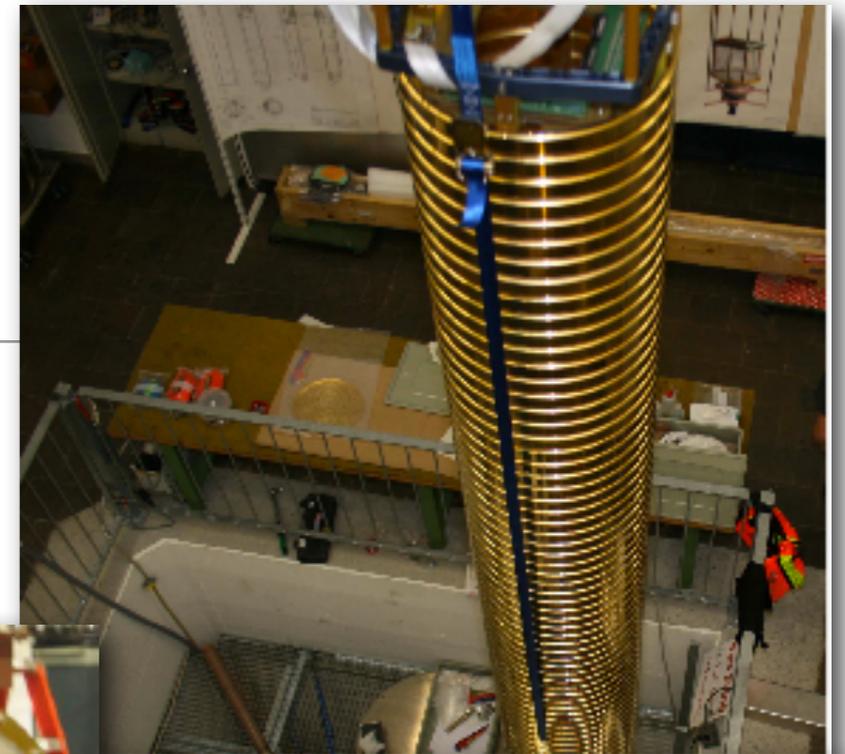

Experiments

- Argontube (Bern): 0.2 m^3 , $L_d = 5 \text{ m}$

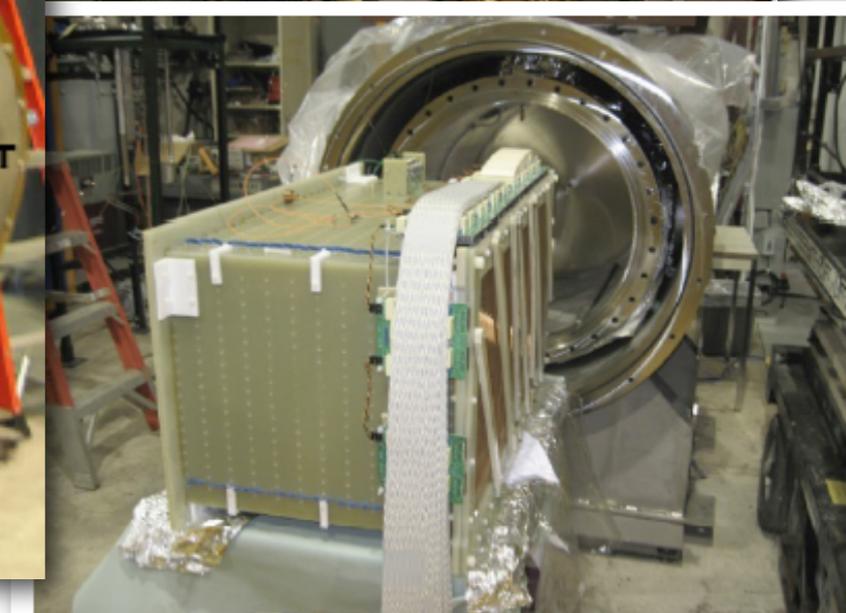

Experiments

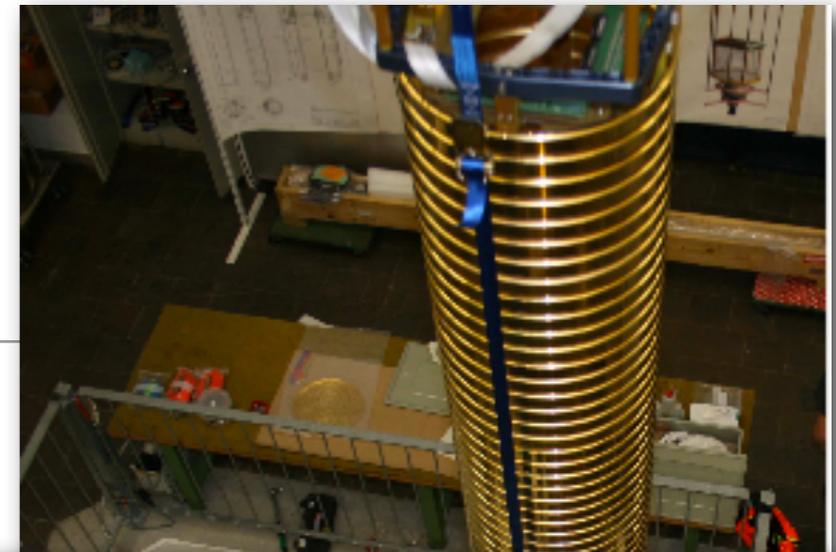

- Argontube (Bern): 0.2 m^3 , $L_d = 5 \text{ m}$
- Argoneut: 0.17 m^3 , $L_d = 0.9 \text{ m}$. Placed in the NuMI beam line in 2009 (between Minerva & MINOS). Neutrino publications

ArgoNeuT 0.76 t

Experiments

- Argontube (Bern): 0.2 m^3 , $L_d = 5 \text{ m}$
- Argoneut: 0.17 m^3 , $L_d = 0.9 \text{ m}$. Placed in the NuMI beam line in 2009 (between Minerva & MINOS). Neutrino publications
- MicroBooNE: $\sim 64 \text{ m}^3$, $2.56 \text{ m} = L_d$ (size of school bus). In Booster beam will turn on at the end of the year.

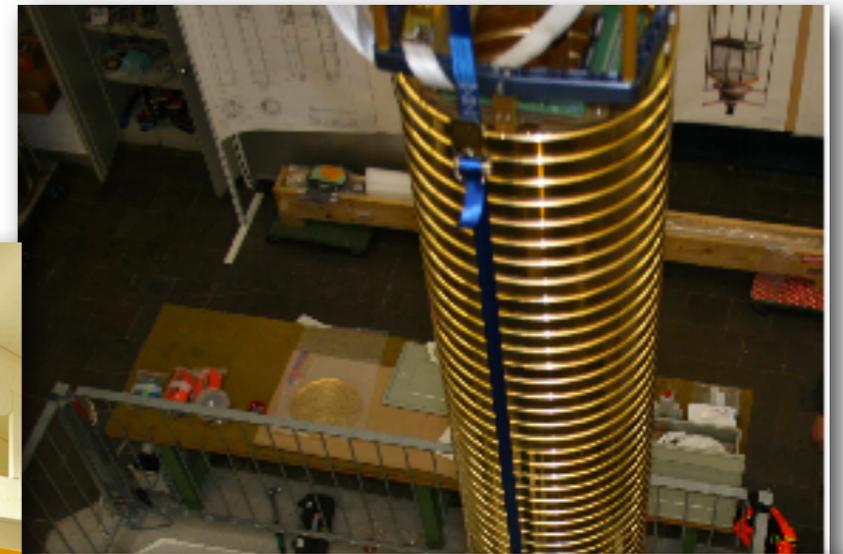

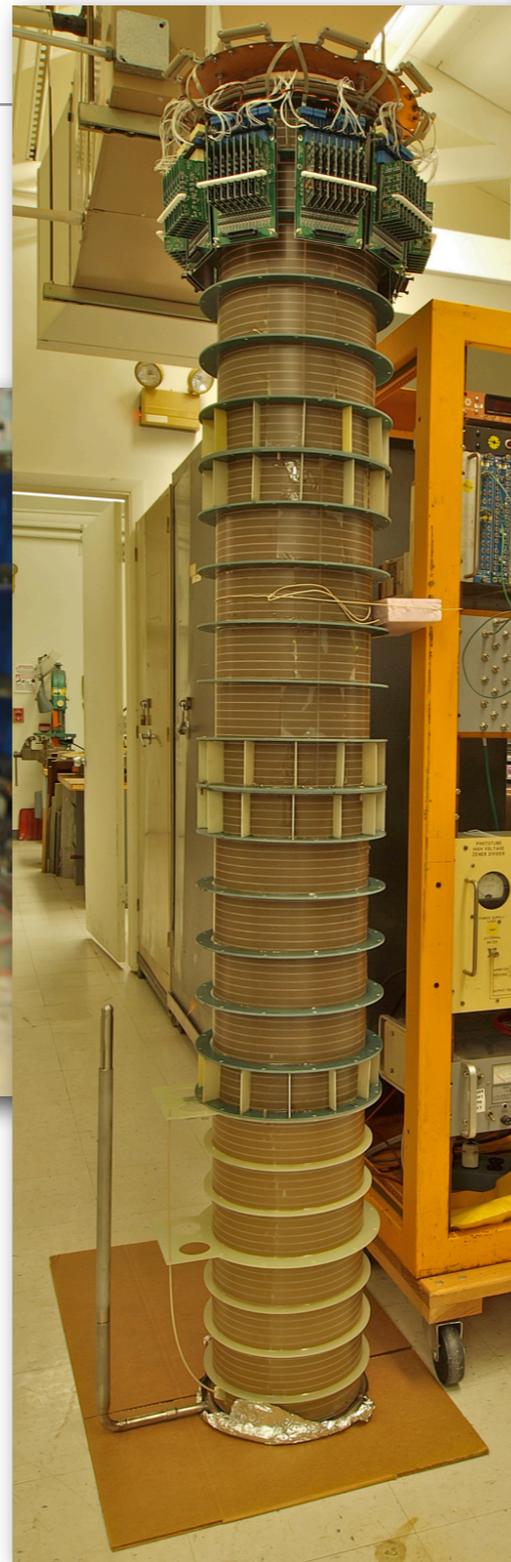

ArgoN

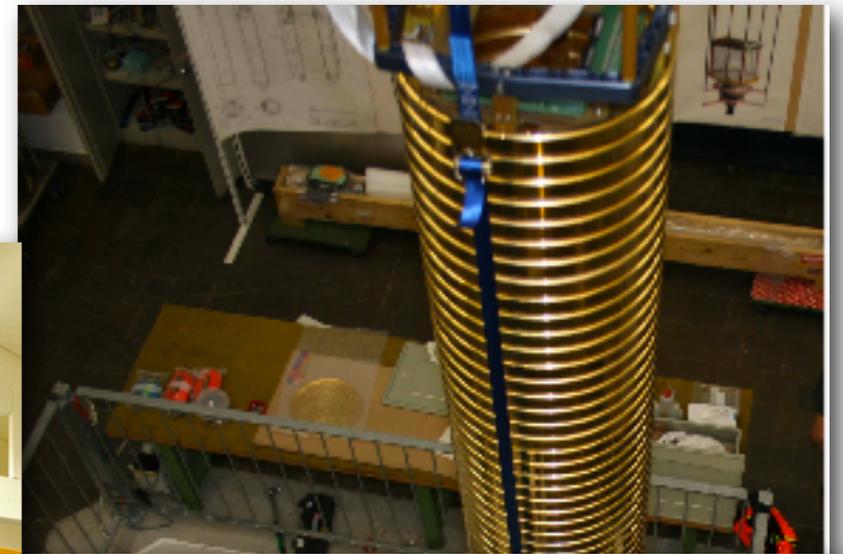

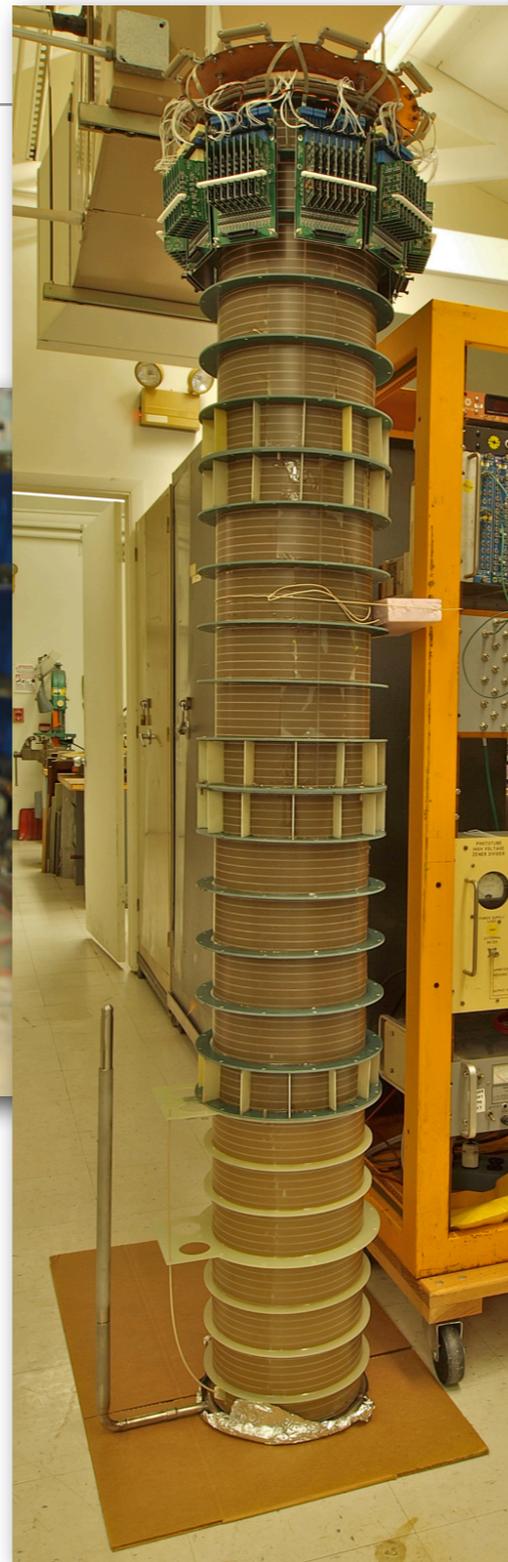

Experiments

- Argontube (Bern): 0.2 m^3 , $L_d = 5 \text{ m}$
- Argoneut: 0.17 m^3 , $L_d = 0.9 \text{ m}$. Placed in the NuMI beam line in 2009 (between Minerva & MINOS). Neutrino publications
- MicroBooNE: $\sim 64 \text{ m}^3$, $2.56 \text{ m} = L_d$ (size of school bus). In Booster beam will turn on at the end of the year.
- Long Bo (Bo): 0.1 m^3 , $L_d = 2 \text{ m}$. Placed in LAPD last year (Bo is one section). Cosmic data

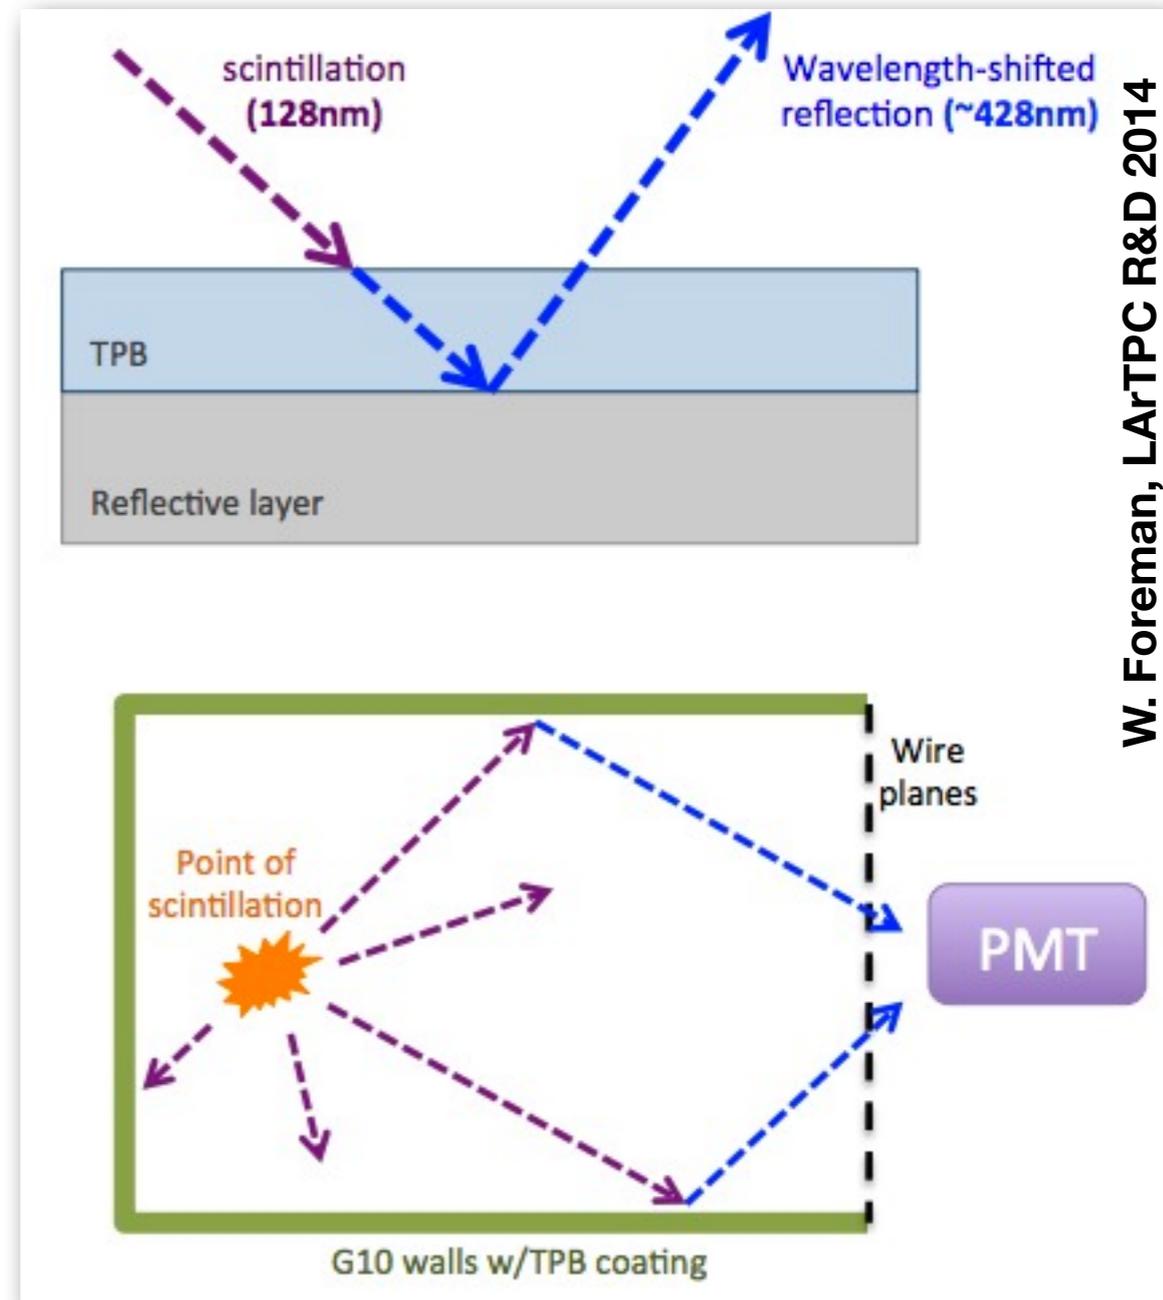

Experiments

- Argontube (Bern): 0.2 m^3 , $L_d = 5 \text{ m}$
- Argoneut: 0.17 m^3 , $L_d = 0.9 \text{ m}$. Placed in the NuMI beam line in 2009 (between Minerva & MINOS). Neutrino publications
- MicroBooNE: $\sim 64 \text{ m}^3$, $2.56 \text{ m} = L_d$ (size of school bus). In Booster beam will turn on at the end of the year.
- Long Bo (Bo): 0.1 m^3 , $L_d = 2 \text{ m}$. Placed in LAPD last year (Bo is one section). Cosmic data
- CAPTAIN (Los Alamos): Idea is to have a mobile cryostat. 0.3 m^3 ; $L_d = 1 \text{ m}$

A Few Words on LArIAT

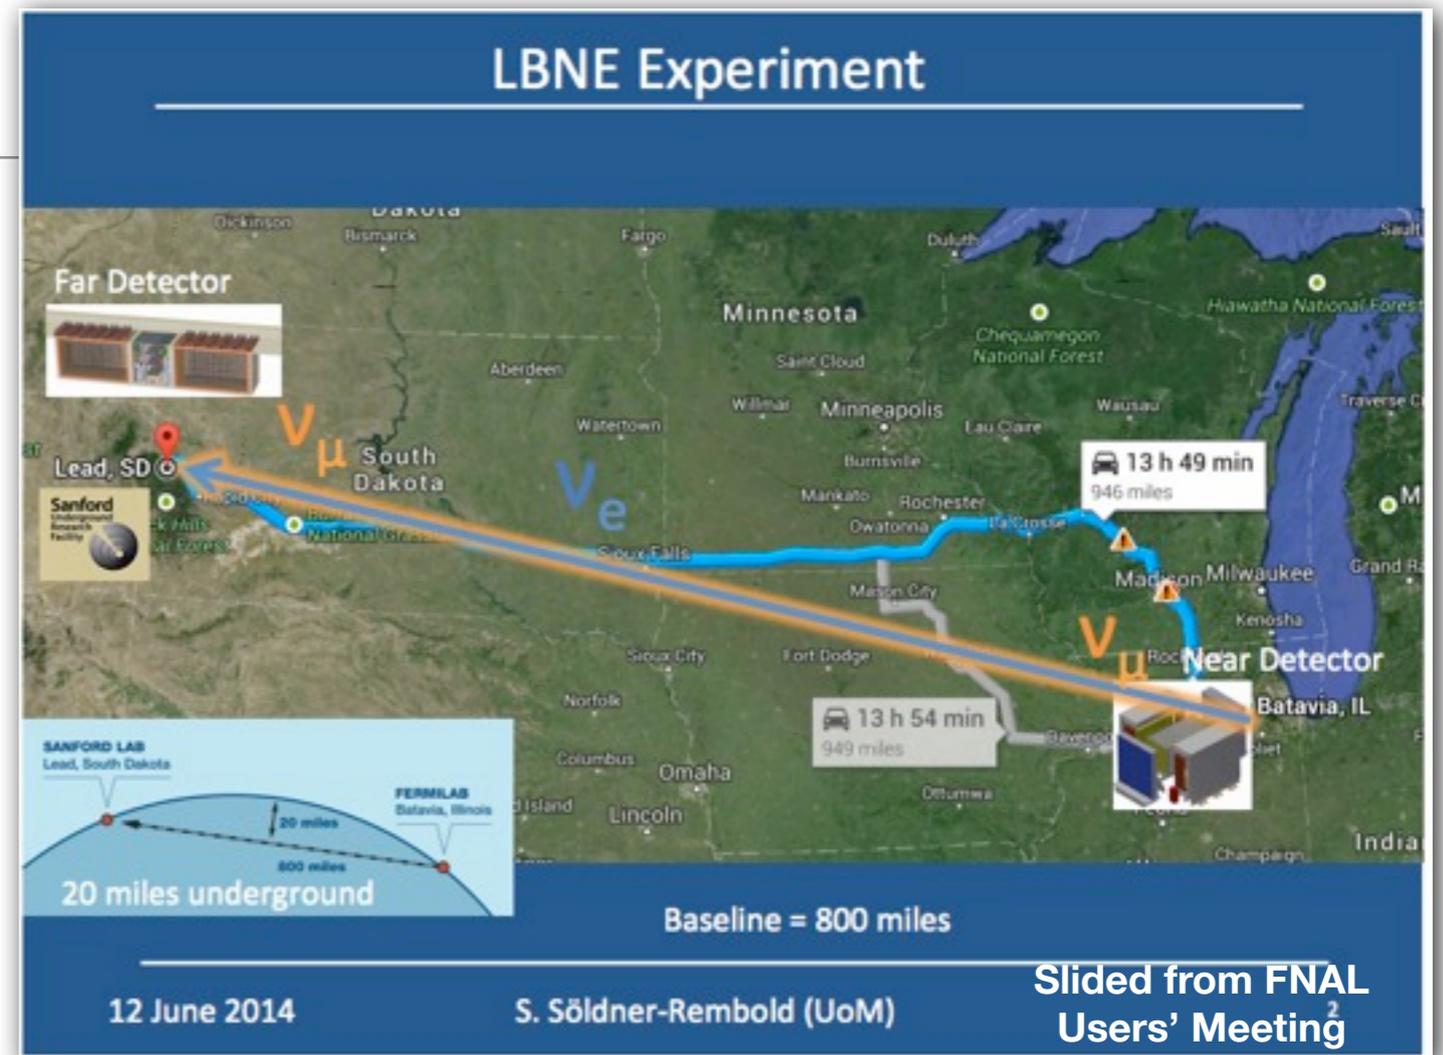

- Resurrected Argoneut -- but better!
- Going in a test beam
 - (Not looking for neutrinos or specifically looking at cosmic rays)
 - Will improve our understanding of how charged particles interact in LAr
- Light collection is different
 - Walls of TPC have the wavelength-shifting coating
 - Want to increase light yield --> improve energy resolution
- Start running by the end of the year

Future Experiments

Future Experiments

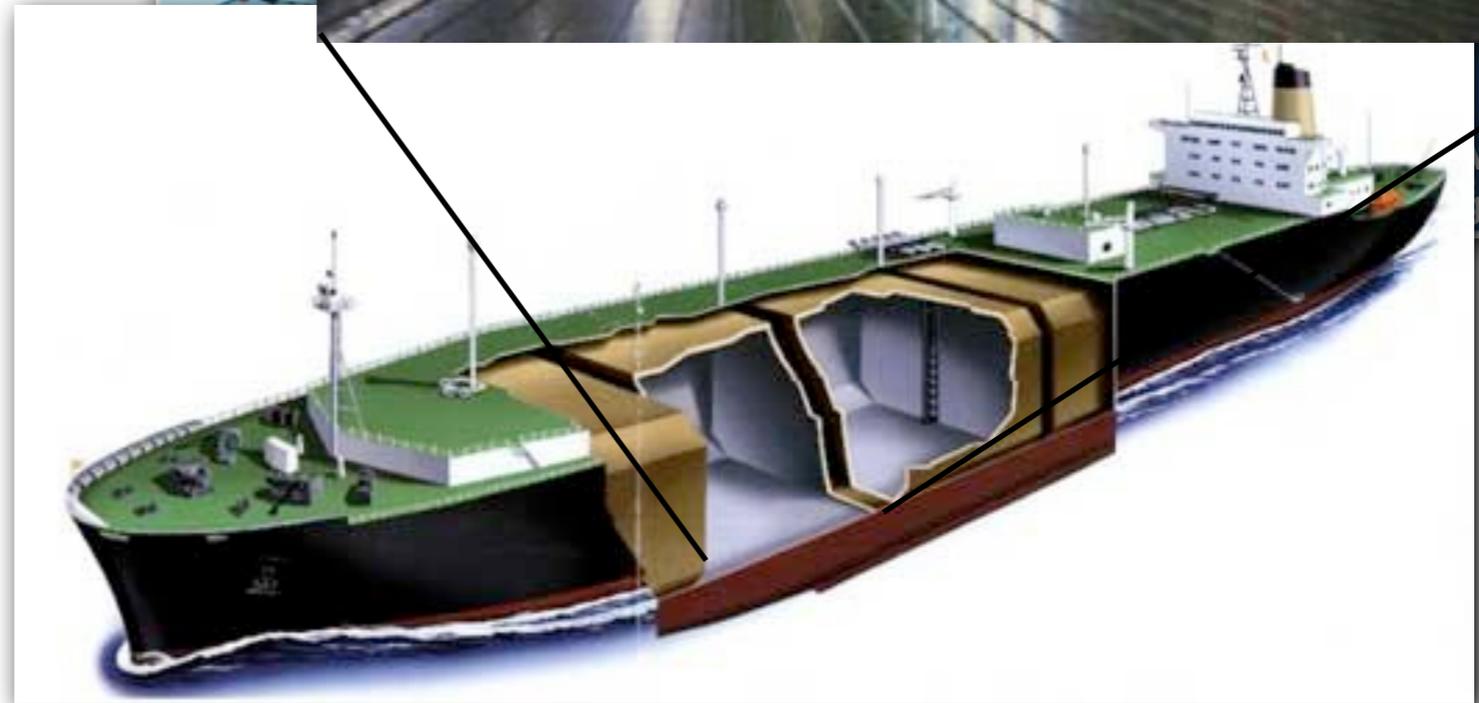

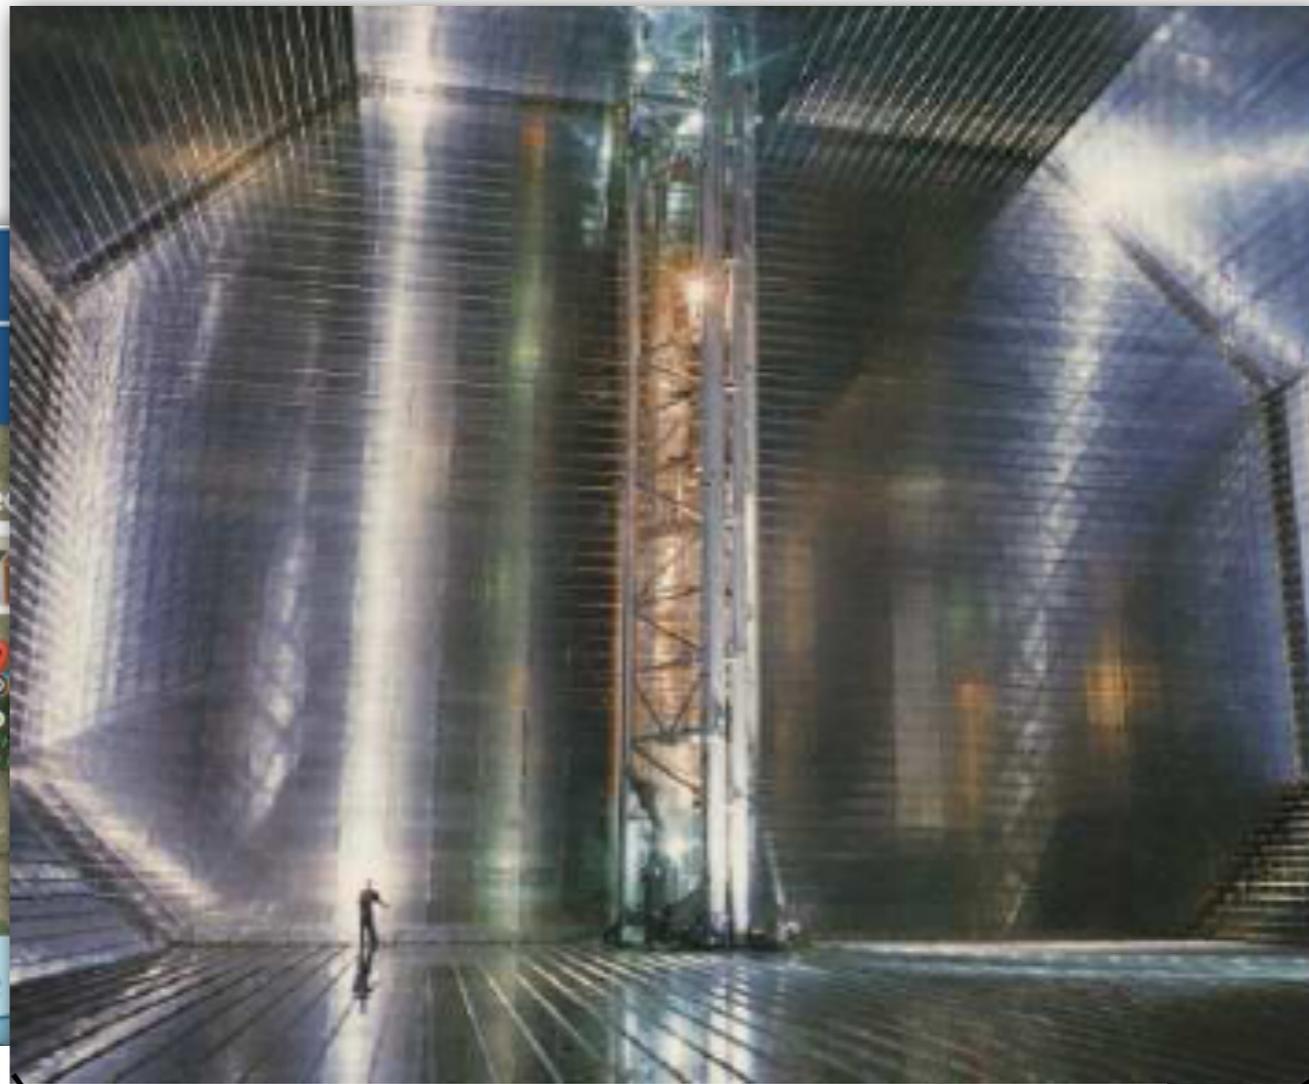

- LBNE(F): Proposed detector in Lead, SD. ~2025+

Future Experiments

- LBNE(F): Proposed detector in Lead, SD. ~2025+
- 35T: R&D/Prototyping for LBNE; membrane cryostat (same as Natural Gas tankers)

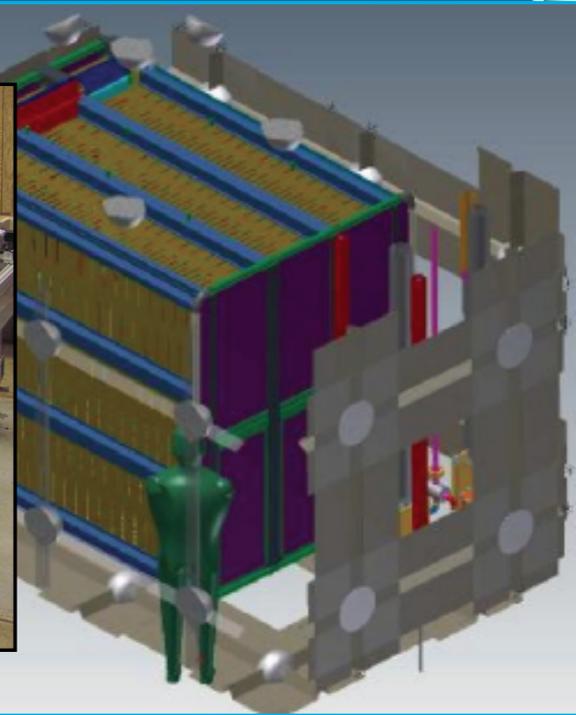

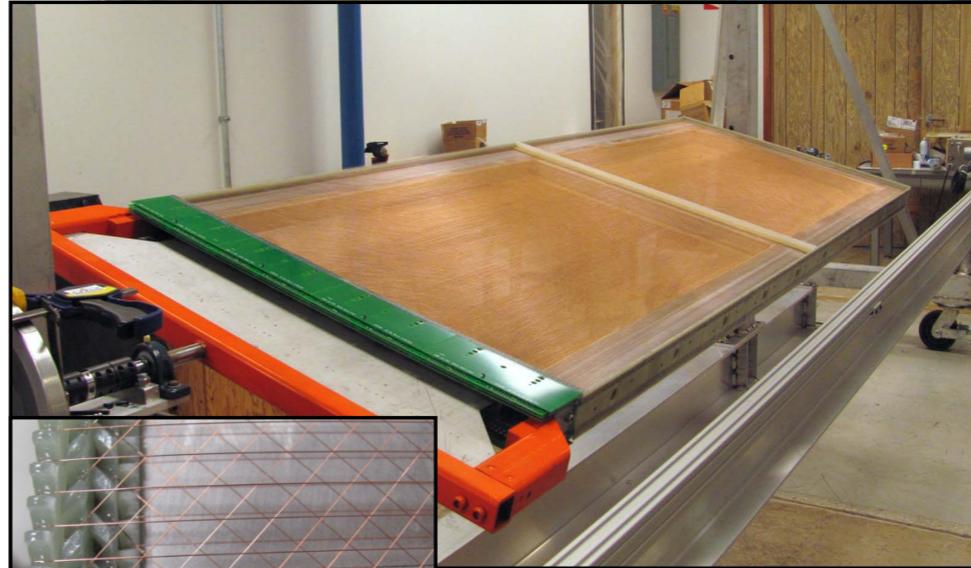

Now!

- GLACIER: European effort; R&D stages; 20 m drift, 20-50 kt; cathode HV at the **MV scale**

Now!

GLACIER

Giant Liquid Argon Charge Imaging experiment

2003 - Glacier concept:

- A. Rubbia, hep-ph/0402110.

2008-2011 - double phase argon TPC proof of principle:

- A. Badertscher et al., Nucl. Sci. Symp. Conf. Rec. (2008) 1328
- A. Badertscher et al., NIM A 617 (2010) 188
- A. Badertscher et al., NIM A 641 (2011) 48

2012 - 80x40cm² charge readout demonstrator:

- A. Badertscher et al., JINST 7 (2012) P08026
- A. Badertscher et al., JINST 8 (2013) P04012

2012-2013 - Further R&D on design simplification:

- paper in preparation

Filippo Resnati - High Voltage in Noble Liquids - FNAL - November 9th, 2013

S. Soldner-Rembold, FNAL Users Meeting

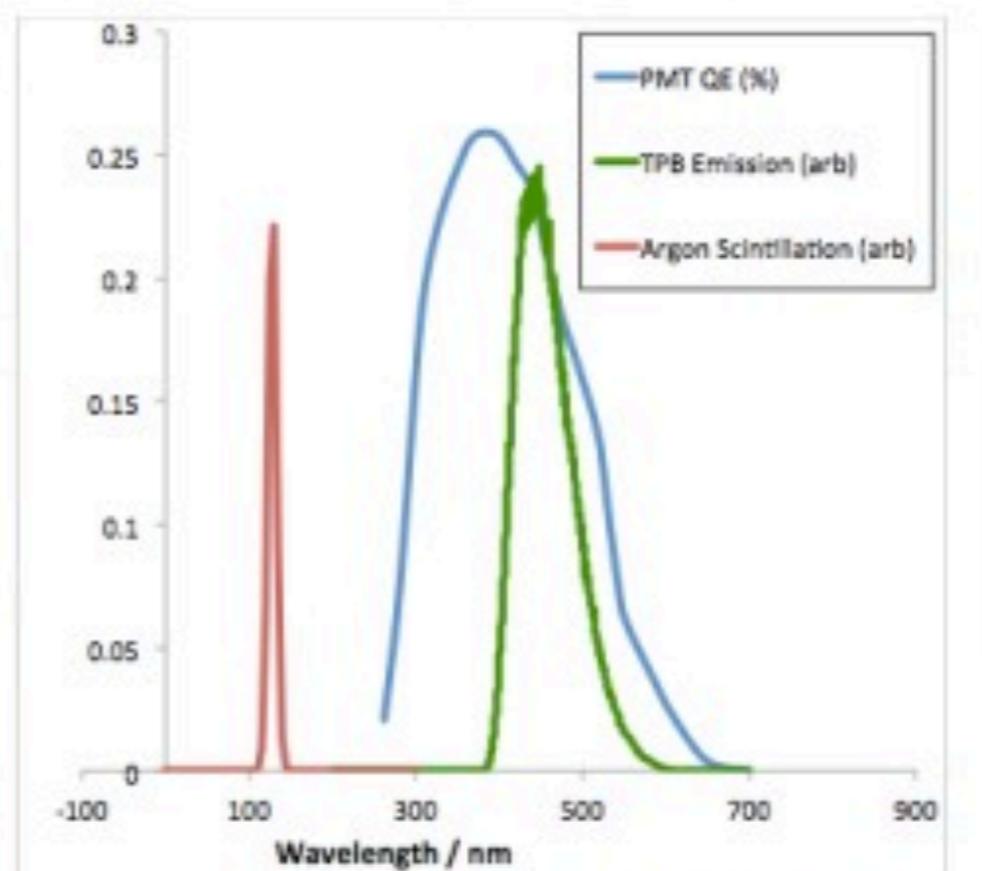

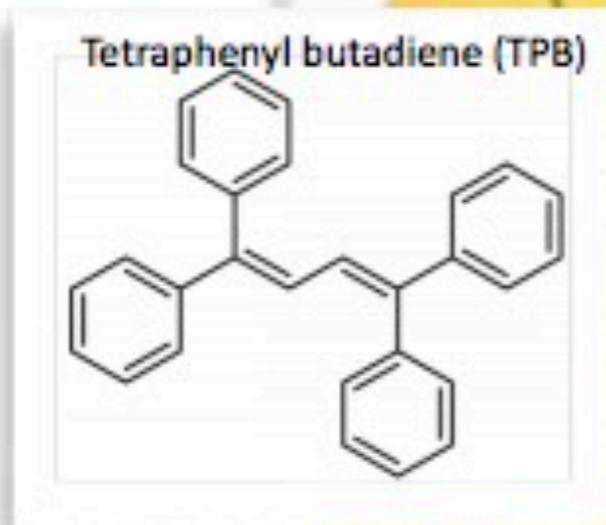

Closing Thoughts...

- I did not cover
 - Physics potential & event reconstruction efforts
 - Dual phase LArTPCs (used in dark matter searches)
 - My apologies if I forgot your favorite LArTPC in the review (feel free to tell me about it)
- LArTPCs are a rich area of research right now -- lots of physics on the horizon & (fun) R&D taking place!

Average Breakdown Voltage vs. Distance

$V_{\text{Breakdown}}$ vs. Distance

- Plotted average V_{bd} at a given distance for a given date's data (specific purity and probe)

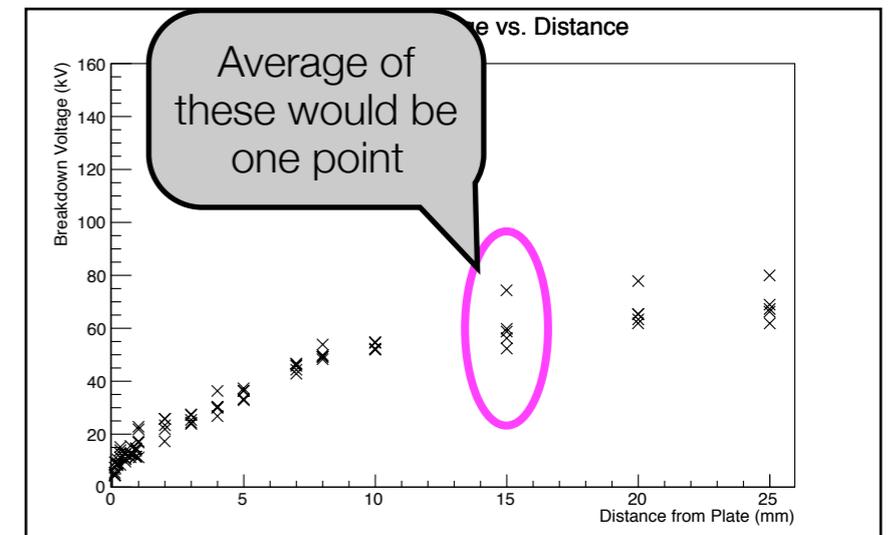

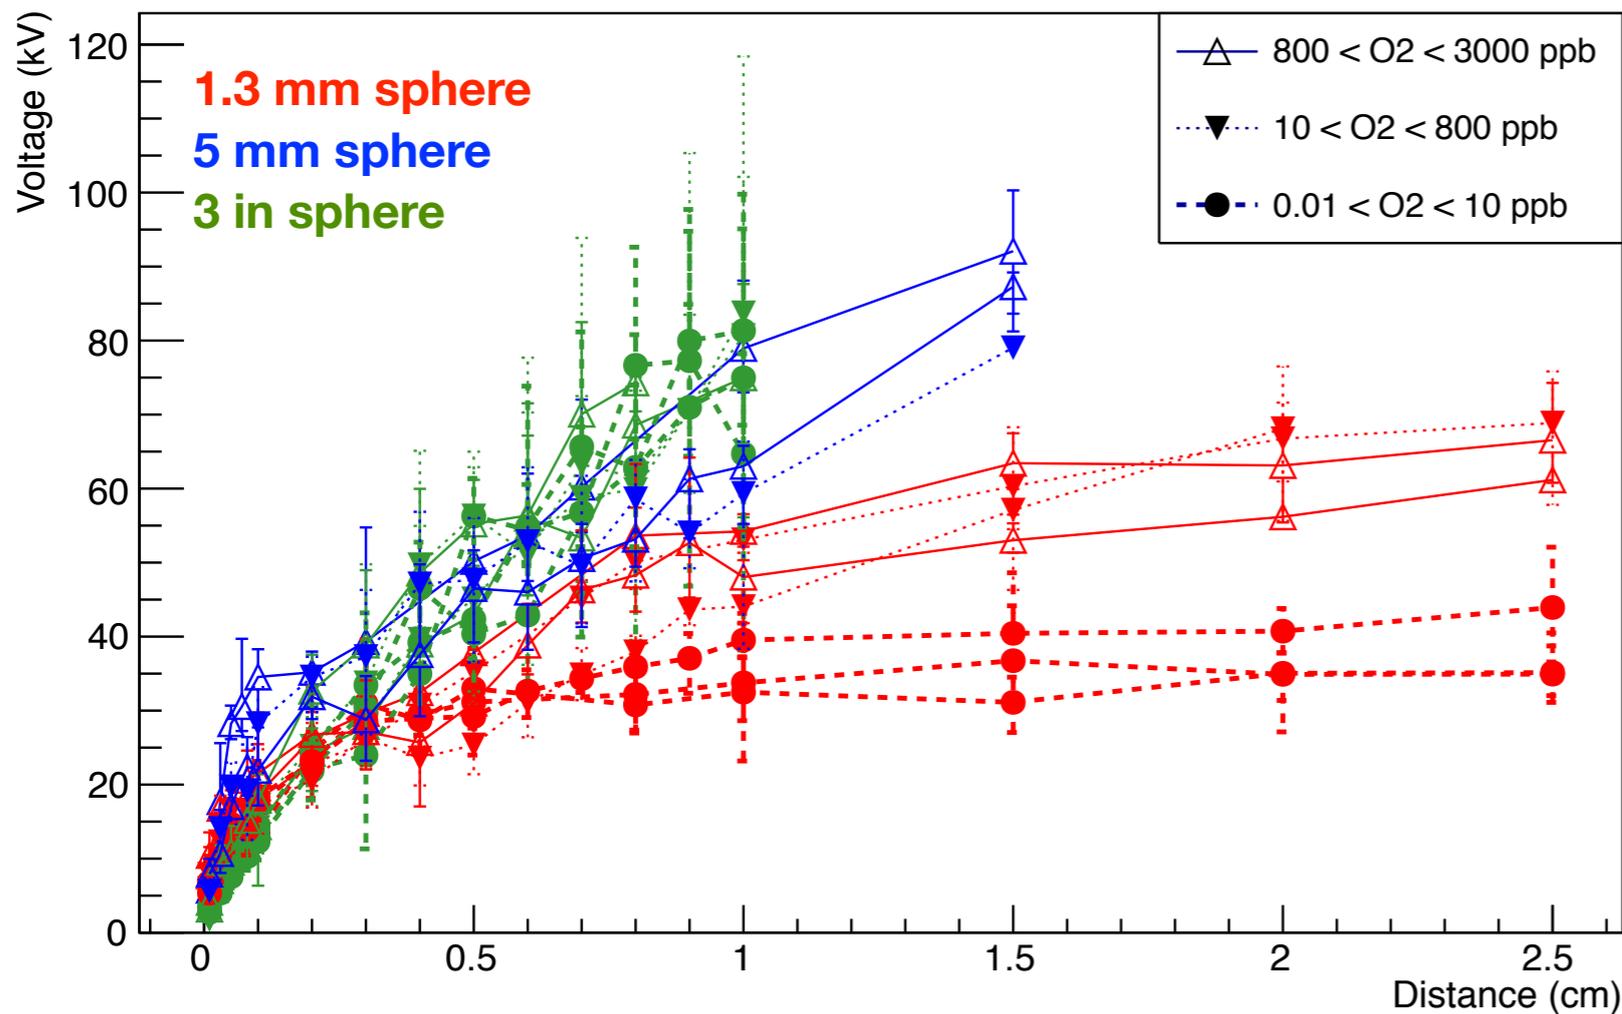

Average Breakdown Voltage vs. Distance

← 10-1400 ppb O₂

← 0.29-1.8 ppb O₂

E_{Max} vs Distance

- Doesn't appear to be just E_{max}

Average Peak Breakdown Field vs. Distance

Other Quantities of Interest

Gerhold *et al.*, *Cryogenics* (1994)

Area effect

The impact of an area effect on LHe breakdown has been recognized by several authors. It is generally accepted that LHe breakdown is triggered at weak-links adjacent to the cathode, i.e. protrusions. The area

Other Quantities of Interest

- Literature suggests a dependence of breakdown voltage on area

Gerhold *et al.*, *Cryogenics* (1994)

Stressed area, peak field is at the star, shaded pink has $E > 80\% * E_{max}$

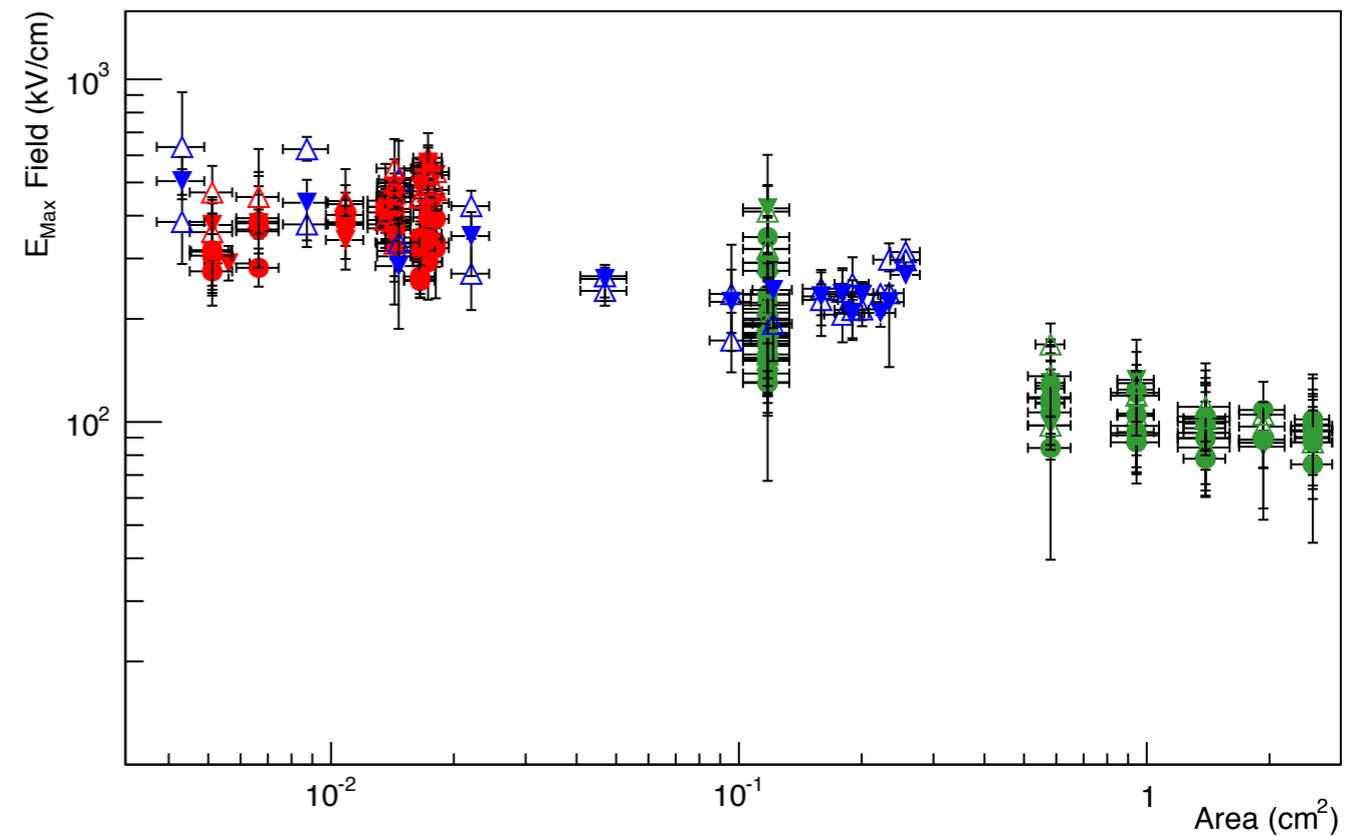

Other Quantities of Interest

- E_{\max} vs Area (80% E_{\max} left; 90% right)

Average Peak Breakdown Field vs. Area with $E > 0.8 \cdot E_{\max}$

Average Peak Breakdown Field vs. Area with $E > 0.9 \cdot E_{\max}$

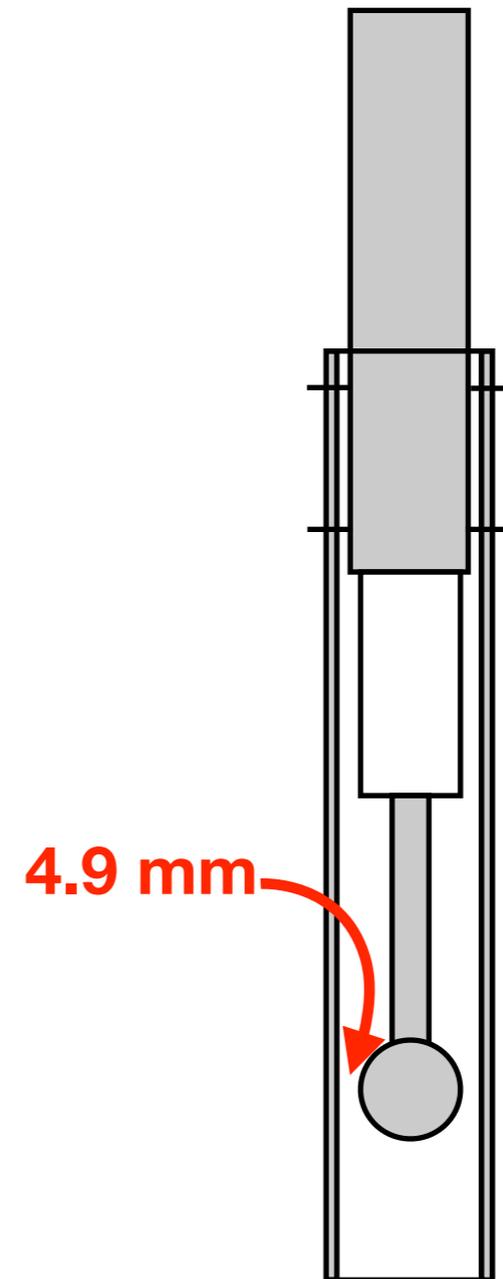

Comparison with another test...

Comparison with another test...

- Last summer we did a breakdown test in LAPD

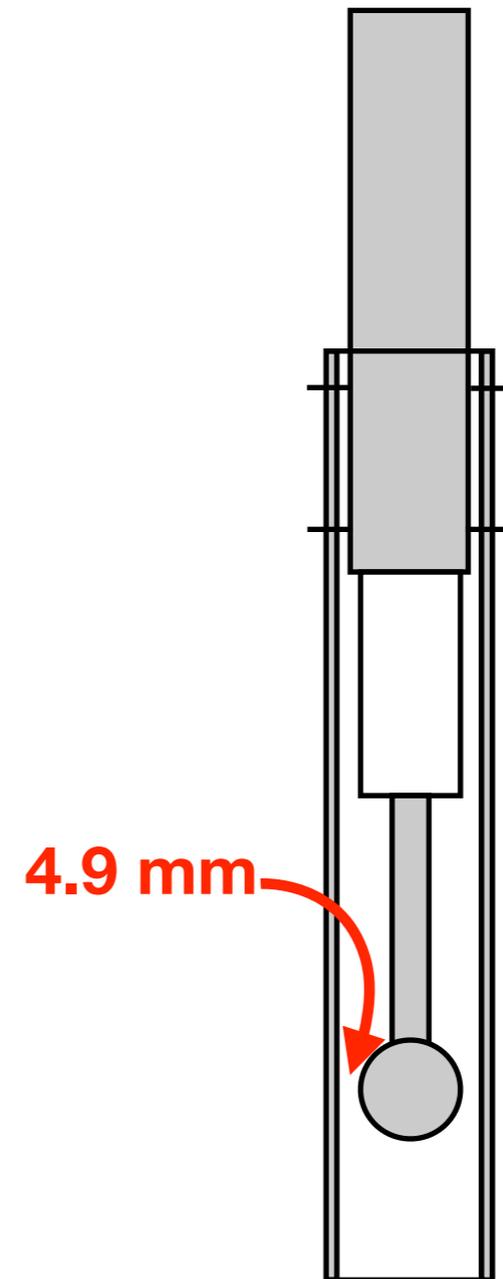

Comparison with another test...

- Last summer we did a breakdown test in LAPD
- We had a 2.5" sphere within a grounded cylinder with a ~4.9 mm gap

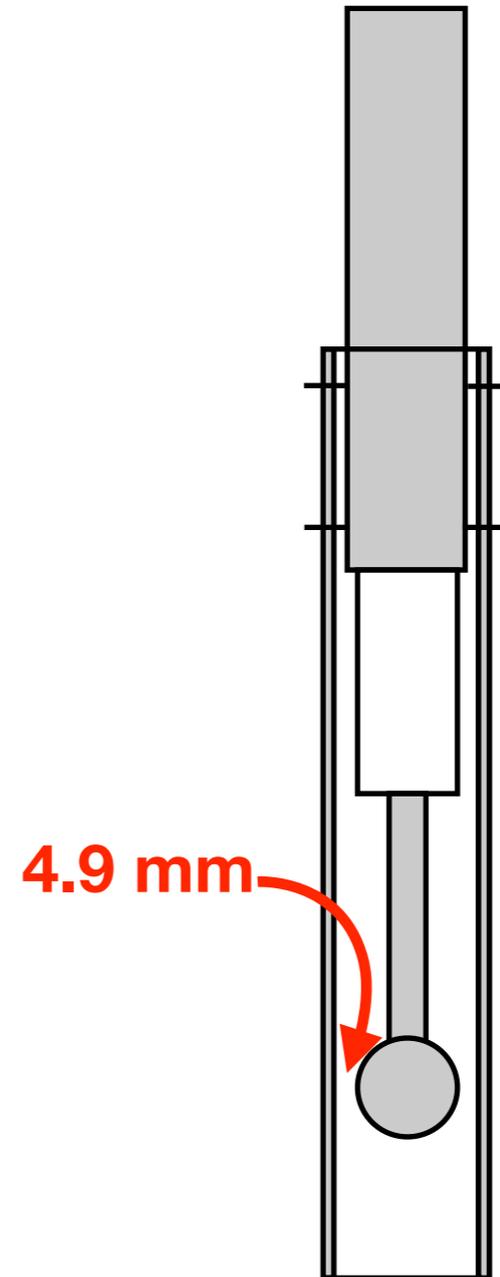

Comparison with another test...

- Last summer we did a breakdown test in LAPD
- We had a 2.5" sphere within a grounded cylinder with a ~4.9 mm gap
- We recorded data with this fixed distance, but...
- There was an issue where a screw was found to be broken after removal

Comparison with another test...

- Last summer we did a breakdown test in LAPD
- We had a 2.5" sphere within a grounded cylinder with a ~4.9 mm gap
- We recorded data with this fixed distance, but...
- There was an issue where a screw was found to be broken after removal
 - (so we likely will not publish this)

Comparison with another test...

Comparison with another test...

- If we assume the device was ok during the testing,
 - We have something with an order of magnitude more stressed area

Comparison with another test...

- If we assume the device was ok during the testing,
 - We have something with an order of magnitude more stressed area
- (80%: 37.6 cm², 90%: 24.7 cm²; E_{max}: ~52 kV/cm)
